In examining channels of communicating emotion, Ekman and Friesen (1969) proposed a controllability-leakage hierarchy of channels of communication. They suggested that the more controllable channels, such as the face, are subject to high accountability on the part of the expresser, elicit external feedback from others, and provide the expresser with internal feedback. This is in contrast to the less controllable 'leaky' channels such as the body and the voice. As such, facial expressions generally express the information that we choose to volunteer (DePaulo, 1992). By contrast, information expressed through less controllable channels such as body movements and the voice may provide a truer window into a person's feelings. This information can still be controlled, but it is more difficult and requires more conscious, deliberate effort (Rosenthal and DePaulo, 1979). In a dramatic illustration of leaky communication, expressions of contempt have been found years later to predict the deterioration of marriages (Gottman, 1998).

In examining how we communicate emotion, there is an often-cited statistic that in communicating one's feelings and attitudes, 93% of the information conveyed is through nonverbal channels versus our words (Mehrabian and Ferris, 1967). However, this is based on a laboratory study that does not account for the wide range of methods available to express ourselves. This is especially true in cases where expressers and perceivers are removed in time and space – such as when one writes a letter to a distant friend – where the verbal channel is the only medium of communication.

Individual Differences in Emotion Expression

In examining individual differences in emotional expression, there have been two distinct operational definitions.

The first approach has been to examine individual differences in expressivity, or how much people tend to 'wear their hearts on their sleeves.' Some individuals have more intense levels of emotional experience and/or more intense urges to express their emotions regardless of their underlying experience (Gross and John, 1998). Expressivity has been conceptualized as a personality trait (Gross and John, 1998; Halberstadt, 1986) because it refers to individual differences in one's way of being rather than producing correct versus incorrect expressions.

The second approach has been to examine individual differences in the ability to express one's emotions clearly so that they can be understood accurately by others. This treats expressivity as an ability – testing if the emotions intended were communicated to others. Emotional expression accuracy – as well as emotion perception accuracy, which is discussed below – is typically considered central to models of *emotional intelligence* (Mayer et al., 2008), as well as the related constructs of *affective social competence* (Halberstadt et al., 2001) and *social skill* (Riggio, 1986). We have an intuitive understanding that controlling emotional displays can be beneficial, e.g., terms like *poker face* exist to explain the benefits of hiding one's evaluation of a situation. Indeed, expressive accuracy appears to be an asset, with greater expression ability associated with positive life outcomes such as workplace performance (DiMatteo et al., 1986).

It is noteworthy that these two distinct ways to conceptualize individual differences in emotion expression – that is, expressiveness versus expression accuracy – tend to be positively correlated, albeit with mixed findings (Halberstadt, 1986; Tucker and Riggio, 1988). An interpretation could be that we become clearer in conveying emotions that we tend to convey intensely – in other words, perhaps practice makes perfect.

Regulation of Emotional Expression

From a young age, we regulate our emotional expressions to be appropriate for the social environment (for a detailed review, see Gross, 2007). However, this regulation comes at a cost – namely, the frustration of holding in the action tendencies and expressive energy that evolved for each emotion (Gross and Levenson, 1993). Notably, e-mail existed relatively briefly before the expressive channel of *emoticons* was invented

(Associated Press, 2007), presumably to reduce the frustration involved with expressing oneself in a text-only medium.

Humans are potentially unique from other species for following norms about displaying affect that match expectations about emotional experience in social contexts (Gallois, 1994; Hochschild, 1983), with display rules to deintensify, intensify, neutralize, and mask displays with qualitatively different displays (Ekman, 1972). This makes the display of emotions an interactive process between the physiological responses and the cultural, social, and interpersonal expectations that shape emotional expression (Scherer et al., 2013). The discussion above of the Organon model emphasizes that pull factors are a matter of deliberate communication – and, as with verbal communication, the messages we choose are shaped by social norms. Returning to appraisal theory provides a theoretical framework to guide what emotions tend to be appropriate in given situations. For example, people expect positive displays when an event is supposed to stay positive, such as when losing, beauty contestants must smile for the winner.

As mentioned above, regulation can come at a cost, if it is accompanied by feelings of inauthenticity or expressive urges being thwarted. In the working world, the concept of emotional labor (Hochschild, 1983) refers to the requirement to express specific emotions on the job, whether or not they are felt, and particularly toward clients, e.g., flight attendants displaying happiness or judges displaying neutrality (Rafaeli and Sutton, 1989). In regulating one's expressions, two major strategies have been identified: surface level, which involves simply changing the appearance of displays, versus deep level, which involves *reappraising* by returning to the appraisal model and reconsidering one's original answers (Grandey, 2003). For example, one can 'look on the bright side' to reappraise valence or find a way to change one's circumstances to reappraise control.

Perception of Emotion

Functions of Emotion Perception

Although the push factors described above emphasize that emotional expression can occur for its own sake, ultimately expressions serve as communication. Each of the modalities for expression described above produces cues that are visible to the social environment, and visible cues can be perceived by others. Brunswik's (1955) general model of perception has been central to research on emotional perception by emphasizing that a psychological state produces cues and cues are recognized, but there is room for error at each of these stages. Looking at the nature of the errors, perception is imperfect not only because we make mistakes but also by design; there may be a kind of 'arms race' between expressers who may wish to shield their emotional state and those who wish to uncover it (Schmidt and Cohn, 2001).

We appear to be hardwired to perceive others' emotions. Encounter with emotional stimuli triggers a rapid neural response that attempts to identify the emotion being perceived. Neural activity identifiable as emotion perception occurs around 100 ms after initial perception of the stimulus, with about 300 ms required before conceptual knowledge of the specific emotion being perceived is activated (Adolphs, 2002). Accumulated evidence suggests neural processes related to emotion are not confined to particular brain regions but involve interaction from various structures in the brain (Lindquist et al., 2012). Although detailed discussion is beyond the scope of the article, perceiving emotional stimuli involves sensory pathways to detect the stimulus, regions of the brain associated with retrieval of memories and conceptual information, and activation of neural systems that facilitate simulation of emotion (Adolphs, 2002; LeDoux, 2012).

Revisiting the Organon model, perception of emotion in others is valuable because expressions of emotions are not only clues about others' internal experience of emotions, but serve as a social signal that offers clues about another person's appraisal of their situation and their likely actions (Campos et al., 1994). Achieving insight into the emotional states of others furnishes one with a survival advantage because a functioning society requires coordination among individuals (Burrows, 2008). Decoding the emotions of others facilitates achievement of shared goals, notably in distinguishing the critical decision to approach versus avoid objects, and the establishment and maintenance of social hierarchies (Keltner and Haidt, 1999; Rosenthal et al., 1979; Schmidt and Cohn, 2001).

Individual Differences in Emotion Perception

A long-standing research program examines individual differences in emotion recognition accuracy and its correlates (Hall et al., 2009; Nowicki and Duke, 1994; Rosenthal et al., 1979). For example, women are better at emotion recognition, as are people of higher education levels and socioeconomic status (Hall et al., 2009; Izard, 1971). As mentioned above, accuracy with emotional expression and perception fall within the larger umbrella of emotional intelligence (Mayer et al., 2008), which has expanded interest in the topic.

There is an advantage to people who can recognize emotions well – better social adjustment, better school performance, and even better workplace success across a wide range of industries and job types (for reviews, see Elfenbein et al., 2007; Hall et al., 2009). That said, being exceptionally good at recognizing emotions can also make people uncomfortable if they feel others are *eavesdropping* on their private feelings (Blanck et al., 1981; Elfenbein and Ambady, 2002).

Given their importance in emotional functioning, are people good at expressing emotions generally good at recognizing emotions? The answer appears to be yes. Accumulated evidence suggests a positive association between expression and perception when expression is measured in terms of an ability (Elfenbein and Eisenkraft, 2010).

Regulation of Emotion Perception

Just as expressers can regulate their displays, perceivers can regulate their interpretations. Decoding rules (Matsumoto, 1989) refer to norms about the appropriate recognition of others' emotions. Perceivers can choose to decode a message inaccurately, or they can decode a message accurately but not allow themselves to respond. Decoding rules can protect perceivers' interests when sensitivity to others' cues may be detrimental. For example, a parent might pretend they did not

witness a display of contempt between two siblings, or tears after their child loses a chess tournament.

Emotional Contagion

Although we have discussed emotion expression and perception as related but separate constructs, and largely as dyadic phenomena, they act together in concert and across multiple individuals. That is, emotions are contagious (Barsade, 2002; Hatfield et al., 1994). Relatively little is known about the mechanisms for *emotional contagion*. The most influential account is *primitive efference* (Zajonc, 1998) – notably that we mimic others' emotional expressions and, through facial feedback, come to experience the same emotions ourselves (Hatfield et al., 1994). However, this mechanism and its magnitude when tested cannot satisfactorily explain empirical findings (Parkinson, 2011). Numerous other mechanisms for the social sharing of emotion have been proposed (Elfenbein, 2014). These include (1) *social comparison*, also called *social appraisal*, in which people compare their feelings with compatriots in order to learn how they are supposed to feel (Barsade, 2002; Parkinson, 2011); (2) *emotional interpretation*, where others' expressive displays serve as information that feeds into the emotional appraisal process and thereby induces emotions (Hareli and Rafaeli, 2008); and (3) *empathy*, or imagining another person's feelings, which is itself emotionally evocative (Davis, 1983; Hatfield et al., 1994). Although most work on contagion focuses on sharing a convergent state, perceivers can also take on a complimentary state (Hess and Fischer, 2013) – e.g., joy in the face of opposing sports fans' disappointment, fear in the face of rage, or contempt in the face of someone's shame.

Just as we may need some minimal perception of other's emotions to converge with them, the reverse can be true in that sharing others' emotions aids the emotion recognition process. The perceiver's own facial expression or activation of facial muscles associated with emotional expression can facilitate or inhibit perception of congruent affective stimuli and also influence the accuracy of emotion perception (Havas et al., 2010; Strack et al., 1988). Along these lines, we may be able to feel our way into perceiving others' expressions.

Cultural Differences in the Expression and Perception of Emotion

Two major mechanisms underlie the cultural differences in emotion that have long been observed, namely norms and styles. Norms govern our display rules and decoding rules, and both of these vary substantially across cultures. Notably, cultures that value greater social harmony tend to inhibit the expression of negative emotion (Mesquita and Frijda, 1992). Styles of emotional expression also vary. According to dialect theory, the specific cues we use to express our emotions – e.g., the configuration of facial muscles, acoustical properties of the voice – differ subtly across cultures (Elfenbein, 2013). Dialect theory was developed to explain the finding of *in-group advantage*, namely that accuracy tends to be higher when perceiving emotions expressed by members of the same versus different cultural group due to greater familiarity.

Abstract

Emotional experience and regulation continue to change in a number of ways through adulthood. In many aspects, such changes appear to benefit emotional functioning. The aim of this article is to review the literature on adult development about emotion, including empirical findings and conceptual accounts of age differences in functioning. We focus on four aspects of emotional functioning: (1) subjective experience, (2) physiology, (3) behavioral expression, and (4) regulation. The discussion of theoretical mechanisms underlying age differences in emotion covers a range of different approaches, including biological, environmental, and motivational.

Life span theories of psychology view development as an adaptive process that continues throughout life and entails both gains and losses (Baltes and Baltes, 1990). Research on psychological aging has primarily focused on loss, particularly cognitive decline (e.g., memory, speed of processing; Craik and Salthouse, 2008). When research on emotion began to accumulate, however, a starkly different picture began to emerge, which suggests a relatively positive trajectory.

In this article, we describe the age-related changes in emotion that occur across adulthood, including shifts in the three core components of emotion, namely, emotional experience, physiology, behavioral expression, as well as emotion regulation. We discuss potential explanations for these changes, including biological, environmental, and motivational accounts. Finally, we propose some promising directions for future research.

Age Differences in Emotional Experience

There has been a great deal of work focused on documenting and understanding how emotional processes develop in childhood and adolescence (Campos et al., 2004; Denham, 1998). Far less research has focused on normative emotional changes in adulthood. When researchers initially began to study emotion and aging, the strong expectation was that emotional experience in late life would be characterized by sadness and anxiety. Despite real losses that come with age, such as the deaths of loved ones and health problems, older adults tend to experience similar or higher levels of emotional well-being than do younger adults (see reviews by Charles and Carstensen, 2014; Consedine and Magai, 2006; Scheibe and Carstensen, 2010). This pattern of findings is often referred to as the 'paradox of aging.'

When study participants are asked about emotional experience, responses typically suggest improvements in emotional well-being across adulthood. Most research on emotion and aging has been cross-sectional and subsequently open to alternative explanations. Older adults today, for example, may be uniquely resilient because of their experiences that are specific to the historical period in which they lived (e.g., Great Depression, World Wars). Longitudinal studies, however, have revealed similar patterns. One of the first longitudinal studies on emotion in adulthood focused on global reports using the Bradburn Affect Balance Scale (Charles et al., 2001). Four birth cohorts were assessed between 1971 and 1994. Consistent with cross-sectional work, self-reported negative experience declined over time. A 10-year longitudinal study using experience sampling at 5 year intervals revealed similar findings (Carstensen et al., 2011). It should be noted that some researchers have found that negative affect is stable or slightly increased in very old age (Davey et al., 2004; Diener and Suh, 1998; Fiske et al., 2003), yet when physical health is controlled, age is reliably associated with reduced negative affect (Gatz et al., 1996; Kunzmann et al., 2000) and Gerstorf et al. (2010) found that closeness to death, as opposed to age per se, better accounts for the increase in negative affect. Thus, the trajectory of emotional experience across adulthood is largely positive until, not surprisingly, illness just prior to death frequently takes an emotional toll.

Even though older adults experience negative emotions less frequently than do younger adults, no age differences have been observed in the intensity of emotional experience (Carstensen et al., 2011; Labouvie-Vief et al., 2003; Levenson et al., 1991; Uchino et al., 1999). That is, once emotions are elicited they are felt as intensely in older as younger ages. The combination of findings about frequency and intensity speak against a general flattening of emotional experience. In addition, as individuals grow older, they are more likely to experience positive and negative emotions at the same time, rather than feeling exclusively positive or negative (Carstensen et al., 2011; Ersner-Hershfield et al., 2008), suggesting comparatively richer and more complex experiences. Importantly, mixed emotional experience is positively associated with resilience (Coifman et al., 2007; Ong and Bergeman, 2004) and good physical health (Hershfield et al., 2013).

Most of the improvement in emotional experience appears to be related to a reduction in the experience of negative emotions. Evidence about changes in positive experience has been mixed. For instance, Diener and Suh (1998) observed a slight decrease in positive emotions with age, whereas Mroczek and Kolarz (1998) observed a modest increase in positive emotions across adulthood. Lawton et al. (1992) suggested that disparate findings may reflect the fact that high

arousal emotions become less frequent with age and many measures of positive emotion tap positive emotions with items like excitement and enthusiasm. Indeed, age-related decreases in negative emotion are most apparent for high arousal states (e.g., anger, rage, despair; Lawton et al., 1992; Phillips et al., 2008; Ross and Mirowsky, 2008; Schieman, 1999). Additionally, Scheibe et al. (2013) recently reported an age-related increase in daily low arousal positive emotions in a sample spanning young adulthood to old age, while high arousal positive emotions were age invariant. They also asked participants about *preferences* for specific emotions and found that older people preferred low arousal positive states (e.g., calm) over high arousal positive states. Compared with younger adults, older adults are generally less focused on increasing positive emotion and more interested in maintaining their existing levels of positive emotion (Riediger et al., 2009). Relatedly, older adults have less moment-to-moment variability in emotional experience, suggesting an age-related increase in emotional stability (Carstensen et al., 2011). Charles (2010) has argued that older people are less able to recover physiologically from prolonged and inescapable arousal and thus may avoid situations that may elicit strong emotions.

Overall, the evidence to date suggests that emotional life becomes less negative and more stable as people age. With the exception of the dementias, older adults have a lower incidence of all psychiatric disorders (Jorm, 2000; Kessler et al., 2005; see review by Piazza and Charles, 2006). Additional research is needed to better elucidate how emotional experience changes with age but the overall profile is clearly positive (English and Carstensen, 2014a).

Aging- and Emotion-Related Physiology

Few studies have examined age differences in emotion-related physiological reactivity. One study found that older adults showed a similar pattern of autonomic nervous system activation as younger adults when posing emotional expressions or recalling past emotional experiences (Levenson et al., 1991). The magnitude of activation, however, was lesser for older adults despite the absence of age differences in emotion expression or subjective reports of emotion experience while recalling past events.

There is evidence that general physiology may change with age in ways that make regulation more difficult. In particular, there is reduced physiological flexibility in both the cardiovascular system and the neuroendocrine system (Graham et al., 2006; Sapolsky et al., 1986; for review see Charles, 2010). As a result, older adults are slower to become physiologically aroused and slower to recover. Consistent with this idea, stressors have been found to elicit less of an increase in heart rate and skin conductance among older adults (Labouvie-Vief et al., 2003; Levenson et al., 1991; Tsai et al., 2000). In addition, in studies of the hypothalamic–pituitary–adrenal (HPA) axis, older adults are slower to return to their baseline physiological state after being exposed to a stressor (for reviews see Björntorp, 2002; Otte et al., 2005). Future research is needed to understand when physiological reactivity is reduced and when it is heightened, as well as whether such changes reflect improved abilities to regulate emotional responses (Magai et al., 2006) or more general changes in physiological reactivity.

Age Differences in Emotional Expression

Aging may impact emotional expressions in at least two ways: the ability to detect emotional expressions in others and the ability to convey one's own emotions. In a study that examined perceptions of posed expressions, older adults attributed less negative emotion to expressions of anger, disgust, fear, and sadness and attributed more unintended positive emotion to these negative expressions (Riediger et al., 2011). Similarly, other studies have found that older adults are poorer at detecting negative emotions in faces than younger adults, whereas there is no age difference in perception of happy faces (Ebner and Johnson, 2009; Ebner et al., 2010). These findings are consistent with the age-related positivity effect, whereby older adults tend to focus on the positive aspects of a stimulus more so than the negative aspects compared to younger adults (Reed et al., 2014; Reed and Carstensen, 2012).

Lab studies that instruct individuals to show specific emotions have not observed age differences in the expression of emotion (Levenson et al., 1991). However, a number of studies have found that others have a more difficult time reading the emotional expressions of older adults (Ebner and Johnson, 2009; Malatesta et al., 1987; Riediger et al., 2011). There is some evidence to suggest that this may be somewhat attenuated in older adult perceivers – that is, older adults may be better at reading the expressions of other older adults (Malatesta et al., 1987; Riediger et al., 2011). However, this advantage for age-matched faces is not a strong or consistent pattern across studies (Ebner and Johnson, 2009; Ebner et al., 2010).

Age Differences in Emotion Regulation

People are not simply at the mercy of their emotions; rather they persistently attempt to influence how they feel and what they express to others. The ability to effectively control emotions is crucial for optimal functioning. Emotion regulation involves a broad range of conscious and subconscious strategies that can be used to control different aspects of emotion (Gross, 1998). Each strategy requires specific resources (e.g., executive functioning, knowledge of the social environment) in order to be optimally successful. With repeated experience, individuals may develop a better understanding of how to use these strategies and which strategies to deploy in which situations. That is, emotion regulation can be considered a knowledge-based skill that individuals hone over time. Given older adults' vast life experiences, there is reason to expect that emotion regulation improves with age.

Older adults do report being better able to regulate their emotions well, especially the experience of emotion (Gross et al., 1997). Consistent with such reports, when asked to regulate their emotions under controlled laboratory conditions, older adults are typically equally or more effective than younger adults (Kunzmann et al., 2005; Phillips et al., 2008), especially when using strategies that draw on past life

experiences (e.g., positive reappraisal; Shiota and Levenson, 2009). There is also some evidence to suggest that emotion regulation becomes less effortful with age, such that regulation requires fewer cognitive resources for older adults. For instance, older adults show less memory impairment after being instructed to regulate their emotions than do younger adults (Emery and Hess, 2011; Scheibe and Blanchard-Fields, 2009).

When older adults choose how to regulate their emotions (in the lab or in daily life), they tend to use more effective emotion regulation strategies (Blanchard-Fields et al., 2004). For instance, they habitually rely less on relatively unhealthy strategies, such as expressive suppression, and more on relatively healthy strategies such as cognitive reappraisal (John and Gross, 2004). Compared to younger adults, older adults tend to have more positive appraisals (Almeida and Horn, 2004; Lachman et al., 2008; Story et al., 2007), they are more likely to tailor their regulation efforts to the specific situation (Blanchard-Fields, 2007) and they use more flexible strategies (Diehl et al., 1996). Older adults are also more likely to meet their emotional goals in daily life (Scheibe et al., 2013).

The literature on social preferences and social networks points to ways that antecedent emotion regulation may be a central advantage that older people have in regulating their emotions. Social networks grow smaller as people grow older, primarily due to a reduction in peripheral social partners (Carstensen et al., 2003). Emotionally close partners are retained so networks have a greater ratio of emotionally close partners as people age. It appears that the overall decrease in network size reflects an active pruning process whereby older adults show an increased preference to spend time in emotionally satisfying and predictable interactions and avoid potentially aversive interactions (Lang, 2000). The shaping of social networks reduces exposure to negative stimuli (Birditt and Fingerman, 2005; Folkman et al., 1987) and facilitates conflict avoidance (Blanchard-Fields et al., 2007; Carstensen et al., 1995; Charles et al., 2010).

Theoretical Approaches to Adult Development and Emotion

Theoretically, aging could benefit emotional experience for a number of reasons. As noted above, aging is associated with changes in biological reactivity (Cacioppo et al., 2011) involving structural decline in emotion-related centers of the brain and slowing of the autonomic system (Cacioppo et al., 1998). Therefore, emotion regulation may become easier because emotions are felt less intensely. Although reasonable theoretically, recent research points to well-preserved functioning in regions of the brain that are involved with emotion memory, threat detection, and reward anticipation (Samanez-Larkin and Carstensen, 2011). Thus, biological and cognitive change cannot fully explain change in emotion across adulthood.

Normative changes, like retirement, may make it easier for older adults to maintain more positive, balanced emotional states (Ginn and Fast, 2006). Some have suggested that social interactions are more pleasant for older adults because others treat them with more respect and are less willing to express negative emotions toward them (Fingerman et al., 2008). One recent study, however, found that increased freedom and leisure time did not fully account for older adults' increased emotional well-being (Riediger and Freund, 2008), and the linear improvements in emotional well-being beginning in early adulthood (e.g., Carstensen et al., 2011) speak against other old-age-specific explanations for improvements.

Another related explanation focuses on life experience (e.g., Blanchard-Fields, 2007; Magai et al., 2006). This perspective places more emphasis on the strengths of older adults and their active involvement in creating their positive outcomes. Older adults have had more opportunities to try to control unwanted emotions and see how different experiences impact their emotional state. With growing experience, individuals may develop emotional expertise that allows them to better regulate their emotions and more flexibly apply strategies in an appropriate manner (i.e., choose the strategy that best fits the situation). Consistent with this idea, older adults have been found to have a better sense of the emotional impact of certain future events than do younger adults (Scheibe et al., 2011).

Socioemotional selectivity theory posits that emotion-related goals are increasingly prioritized across adulthood due to shortening time perspectives (Carstensen, 2006; Carstensen et al., 1999). With age, as increased constraints are placed on time left in life, individuals focus their resources on goals that can be realized in the moment (emotional satisfaction and meaning) rather than more future-oriented goals (exploring, expanding horizons). Many studies have provided support for an age-related shift in motivation (for a review, see Carstensen, 2006). Socioemotional selectivity theory postulates that as people age they become increasingly selective in their choice of social partners and activities, investing increasingly in a smaller set of important people. A recent longitudinal analysis of social network change over time supports this claim. The reduction in network size appears to be driven by reductions in acquaintances while the inner circle of close family and friends is retained and concomitant improvements in daily emotional experience accompany these selective reductions (English and Carstensen, 2014b).

Because goals direct cognitive resources, older adults may focus more on emotional information (given its goal relevance, based on socioemotional selectivity theory), especially positive information (given its emotional benefits). Tests of this hypothesis led to the identification of the *positivity effect* in attention and memory; Older people reliably attend to and remember positive information (Mather and Carstensen, 2005; Reed and Carstensen, 2012) and this selective cognitive processing may benefit emotional experience and regulation (Isaacowitz et al., 2008).

The model of strength and vulnerability integration (SAVI; Charles, 2010) combines motivational and knowledge perspectives, positing that older adults are often better able to regulate their emotions (and thus have higher emotional well-being) because of their accumulated experience and self-knowledge, as well as their heightened emotional goals. Due to their physiological vulnerability (i.e., reduced flexibility), however, the model predicts that older adults may not regulate as well in situations that are emotionally intense or prolonged. A similar line of argument suggests that older adults avoid negative and arousing stimuli in an effort to conserve limited cognitive and physical resources (Heckhausen and Schulz,

1995; Labouvie-Vief, 2003). Fortunately, older adults are often able to avoid these kinds of stressors in daily life and as a result they tend to experience less negative affect (Charles et al., 2010).

Future Directions and Conclusions

Research on emotion and aging began only about two decades ago. Initial expectations that old age would be associated with sadness, fear, and despair have not been supported. On the contrary, emotional experience seems to improve with age. Recent studies have also revealed age-related improvements in the ability to regulate emotion. However, many questions remain. We end this article by discussing two promising areas of future research: (1) Intraindividual change in emotion across adulthood and (2) Mechanisms underlying age-related changes in emotion.

There have been a number of cross-sectional studies comparing different aspects of emotion in younger and older adults. These studies have revealed some positive trends, such as improved emotional well-being and ability to regulate emotion later in life. The longitudinal studies that exist also tend to find similar age-related improvements in emotion when tracking individuals as they age. More longitudinal studies are needed to better understand how emotional processes develop across adulthood. In particular, there is a pronounced lack of longitudinal studies focused on the trajectory of emotion regulation, emotional expressivity, and physiological reactivity. These kinds of studies not only can provide better insight into normative trends (i.e., how individuals typically develop emotionally) but also can provide some information about individual differences in change across adulthood. Despite the fact that, on average, individuals show improvements in certain aspects of emotional well-being and regulation, there are individuals who do not show this pattern (e.g., perhaps those who are more neurotic or socially isolated). Future work that is focused on intraindividual shifts in emotion is critical in order to improve the ability to predict who may be at risk for adverse emotional outcomes later in life.

Another important direction for future work is isolating the mechanisms underlying the age-related shifts that occur in emotion. Theoretical explanations span experience-based improvements in emotion regulation to biological deterioration. The motivational account offered by socioemotional selectivity theory (Carstensen, 1992) has been most widely examined. SAVI (Charles, 2010) offers an integration of socioemotional selectivity theory and evidence that in some contexts aging may no longer be protective. Importantly, extant conceptual accounts are not mutually exclusive. In all likelihood, motivation, experience, and biological changes each contribute to emotional experience in later adulthood. Additional studies are needed that address each of these potential mechanisms and examine the role they may play in driving changes in emotional experience, expression, physiology, and regulation.

Abstract

Experiencing health problems can produce strong emotional responses that may impact psychological well-being and disease outcome. Also emotional states have been found to be associated with the development of disease. Negative emotions have been found to be associated with health complaints. Conversely, positive emotions have been found to be associated with better health. Emotions may affect health indirectly by influencing behaviors known to be associated with health outcomes or through physiological mechanisms such as physiological reactivity and changes in immune functioning. Approaches for helping people deal more effectively with negative emotions and maximize positive ones are discussed.

Emotions have long been believed to play a significant role in health. However, definitive evidence on the nature of this role and the mechanisms involved is still being developed. On the one hand, patients often have emotional reactions to the diagnosis of serious or life-threatening illness that can influence psychological as well as physical well-being. On the other hand, emotions and their expression or inhibition have been linked with the development of various disease conditions. This article explores what is currently known about these links between emotions and health and the implications for both theory and intervention.

Following a period dominated by behaviorism and stimulus–response approaches to behavior, there has, of late, been an explosion of interest in the emotions, their nature, antecedents, and consequences. Beginning in the 1980s, this interest has been brought about by a growing acceptance of a cognitive meditational approach to human behavior, which goes beyond a simple stimulus–response model of human behavior to seeing behavior as being strongly mediated by internal psychological processes of which, of course, emotions are a part (Lazarus, 1993). However, there still remains a dispute on the nature of emotions and their definition, which is beyond the scope of this article. For the purposes of this article, we follow the general consensus of the definition in which emotions are seen as the affective states, which can be differentiated into identifiable valenced qualities, are embedded in a social and cultural context, are experienced internally (subjective feeling), manifest themselves on a behavioral level (e.g., as emotional expression), and are associated with identifiable patterns of physiological activity.

There is consensus on the functional note of emotional states in the first place – negative emotions are in many situations adequate and serve important psychological and social functions. However, in many cases emotions might interfere with goals and need to be regulated. In recent years, *emotion regulation* has been subject to an increasing amount of research. It is defined as the shaping of which emotion is experienced and expressed when and to what extent (Gross, 2014). Emotion regulation can be automatic or occur under awareness and may engage in different phases of the experience of an emotion (e.g., before the full blown emotional experience evolves or afterward). (Dys-)functional emotion regulation is seen as a core feature of mental health and of high relevance in the context of physical health. Prolonged negative affect resulting in depressive or anxiety symptoms can be conceptualized as a dysregulation of mood. Recently, the importance of interpersonal processes in emotion regulation has been receiving increasing attention in research (e.g., Debrot et al., 2013). The examination of the links between socioaffective factors and physical health is a promising venue in the search for psychological pathways to physical health.

We focus on emotions as both consequences and antecedents of physical illness. Thus, we begin our discussion with a consideration of the emotional responses to illness (and how they are regulated) and then move on to a discussion of emerging evidence for the role of emotion in the development of disease.

Emotional Responses to Illness

Recognizing the importance of emotions in illness states, Leventhal and his colleagues developed the self-regulation model with a parallel-response framework, which combines a cognitive and an emotional path (e.g., Leventhal et al., 2001). The cognitive path consists of the psychologically 'objective' representation of the health threat with its coping procedures and evaluative processes, whereas the emotional path consists of the 'subjective' or emotional processing system, which creates feeling states, and the coping procedures and appraisal rules for the management of the system.

A wide range of emotional responses can appear at various stages of a health problem in response to related symptoms, diagnoses, and treatments. Emotional responses experienced in the face of illness often lessen with time as the person comes to grips with the condition but can lead to serious emotional maladjustment. Key determinants of quality of emotional adjustment appear to be age, the severity of the condition, coping and emotion regulation strategies, and social support. Coping strategies appear to be critical determinant of emotional adjustment. For example, positive adaptation to breast cancer appears to be facilitated by finding a sense of

meaning in the experience of cancer as well as developing a sense of mastery and control over the disease and using downward comparison to help one feel good about how one is doing in the face of the disease (Taylor, 1983). Finally, the sociointerpersonal context is considered as highly relevant for the emotional adjustment to stress and traumatic experiences (Maercker and Horn, 2013; for example, having supportive social relationships is critical to positive adaptation).

Emotional responses to serious illness can also have important implications for the person's physical well-being. For example, 10-year survival rates for breast cancer patients who responded to their diagnosis with feelings of helplessness, denial, or stoic acceptance have been found to be substantially lower than those for patients who responded to their diagnosis with what has been termed a 'fighting spirit,' which included optimism in the face of their disease and a determination to do everything in their power to overcome the disease (Pettingale, 1984). Furthermore, affective symptoms after a cardiac event are highly predictive not only of psychosocial adjustment but also of physical health-related outcomes. For example, depression following myocardial infarction is associated with a more than twofold increased risk for all cause of mortality (Meier et al., 2011). Particularly, depressive and anxiety symptoms and their associated mood dysregulation are highly linked with the progression of cardiac diseases. Studies show that treating mood disorders after a cardiac event can improve the adjustment process and save health care costs (Ladapo et al., 2012). In general, it can be stated that physical conditions often lead to affective response that, if dysregulated, can translate into affective symptoms and mental health problems such as depression, anxiety, adjustment disorder, and traumatic symptoms. In a meta-analysis in the context of cancer, up to one-third of the researched patients showed clinically significant disordered mood (Mitchell et al., 2011). Thus, life-threatening events such as acute coronary symptoms can provoke posttraumatic affective symptoms, which in turn are associated with worse clinical outcomes (Edmondson et al., 2012).

Emotional responses to physical health problems do not emerge in a social vacuum and may be shaped as a function of individuals' social identities and their relationships with others. For example, the collective self predicts the experience of emotions such as shame and embarrassment in the context of physical health problems, which are likely to result from one's failure to participate successfully in an interdependent relationship, or from doing harm to a relationship (Uskul and Hynie, 2014). Thus, individuals whose self-definitions are derived from their memberships in in-groups or social categories are more likely to experience health problems in terms of how this situation may impact social others and their relationships with them. This is further supported by findings indicating that the endorsement of collective self is associated with the experience of social concerns, concerns that relate to how the health problem will impact significant others' lives or one's relationships with them (Uskul and Hynie, 2007).

Emotions and the Development of Disease

Emotions have also been linked to the development of a variety of disease conditions. In what follows, evidence is examined concerning emotions that are associated with a higher risk of disease as well as others, which appear to be protective against ill health.

Emotions as Health Risk

Not surprisingly, emotions associated with increased risk of disease are negative ones. Evidence has accumulated linking various negative affect to the experience of ill health as well as the development of various disease conditions (Kiecolt-Glaser et al., 2002). Further, there is a tendency for the experience of different negative emotions to be correlated with each other and as such it makes sense to refer to a general tendency toward the experience of negative emotions. This tendency is known as negative affectivity and is closely related to the personality trait of neuroticism. A number of studies have found negative affectivity to be common ingredient running through various health-related measures of stress, emotion, coping, and illness experience. As such it has been argued that findings relating such measures as life stress, pessimism, loneliness, low-life satisfaction, and other measures of psychological distress to poor health can be explained, at least in part, as being a reflection of this general tendency to experience negative emotions and interpret experience in negative terms (Clark and Watson, 1991). Other evidence indicates that it is not just the experience of negative emotions that is associated with poorer health but more specifically the lack of expression of these emotions. Since the 1980s, research evidence has been accumulating on the negative health effects of emotional inhibition. In particular, people with repressive coping styles as well as those actively inhibiting the expression of emotion have been found to have generally poorer health and to show negative psychophysiological as well as immunological changes as a result of suppressing the expression of negative feelings (Pennebaker, 1995).

Although these general variables of negative affectivity and emotional inhibition are associated with poor health generally, there is also good reason to believe that a full understanding of the relationship of emotion to health requires examination of the ways in which specific emotions relate to health status and to specific disease conditions. In particular, the relationships of different emotions to specific health conditions are somewhat variable, suggesting at least a certain amount of specificity in the role of emotions in health. Numerous studies have found significant associations between anger/hostility and deaths from coronary heart disease (CHD) as well as mortality from all causes, an association that remains significant when other risk factors are statistically controlled for (Siegman and Smith, 2013). Anger and hostility also appear to be related to other disease conditions such as cancer and arthritis but the strength of these relationships tends to be somewhat weaker than that found with CHD. Depressive mood is a second emotional state with significant health implications. The most obvious association between depression and health is with suicide. However, depression has been found to have an association with a number of other medical conditions as well. A bidirectional association between depression and medical conditions is assumed. On the one hand, there is evidence that depression is associated with an increased likelihood of conditions such as heart disease and cancer as well as with overall mortality

(Wulsin et al., 1999). On the other hand, depression has been found to be associated with poorer prognosis for patients diagnosed with conditions such as AIDS, cancer, and heart disease. For example, meta-analyses show depression to be a significant predictor of mortality among cardiac patients (Barth et al., 2004) whereas similar findings have been obtained for cancer patients with a 25% increased mortality rate for patients reporting even subclinical depressive symptoms (Satin et al., 2009). Relatedly, grief has been found to have significant health implications. Several studies have shown increased illness as well as mortality among individuals who have been recently bereaved (Stroebe et al., 2007). Socio-affective pathways are also suggested to play a role in the established link between divorce and mortality (Sbarra et al., 2011). More recently, the experience of more social emotions have been linked to physical health. For example, individuals who experience the highest levels of shame in situations involving social-evaluative threat also report the highest increase in cortisol (Kemeny et al., 2004). Moreover, individuals who experience shame in a task that induces self-blame show the greatest elevations in proinflammatory cytokine activity, while guilt and general negative emotions are not associated with cytokine changes (Dickerson et al., 2004).

Emotions as Protector of Health

The flip side of the coin is that positive emotions may be protective of health (Salovey et al., 2000). Evidence for this is not as strong as for the effects of negative emotions but links are being established. For example, positive emotional experience in early life is associated with longevity 6 years later (Danner et al., 2001) and positive affect predicts 2-year survival rates in an elderly population (Ostir et al., 2000).

A well-established piece of evidence for positive emotions as a protector of health comes from work on optimism. Optimism refers to a person's tendency to look on the positive side of events and to believe that events will work out for the best. As such optimists can be expected to experience positive emotions more often than more pessimistic individuals. Research on optimism indicates that optimists tend to live longer, healthier lives than more pessimistic individuals and also to be less susceptible to viral infections, such as the common cold. In addition, optimistic cancer patients tend to live longer than more pessimistic ones and optimism is associated with greater immune system competence as indicated by the ratio of T4 to T8 cells (e.g., Kubansky et al., 2001).

More recent work has investigated two other positive emotions and health, namely hope and curiosity, and shown that, across hypertension, diabetes mellitus, and respiratory tract infection, higher levels of hope and curiosity were associated with lower levels of disease development (Smart Richman et al., 2005). This evidence further contributes to past research showing the protective role of positive emotions in the development of disease.

Until recently, research examining the role of emotions in health outcomes has been limited to studies in developed countries in the West. Asking whether the emotion–health connection is a first-world problem, Pressman et al. (2013) have used survey data from individuals from 142 countries asking about positive and negative emotions and self-reported health and found that both positive and negative emotions have a unique and moderate association with self-reported health. These associations remain when controlling for data on food, shelter, and safety. Associations between positive emotions and health are stronger in low-GDP countries compared to high-GDP countries. Thus, the emotion–health link seems not to be limited to developed countries, but can be observed across the globe.

In a more fine-grained cultural analysis of the emotional–health link, Miyamoto and Ryff (2011) show that experiencing both positive and negative emotions moderately frequently, thus experiencing both types of emotions in a balanced manner, is associated with fewer illness symptoms among Japanese, but not among Americans. Such balanced experience of positive and negative emotions among Japanese has been claimed to assist them in showing a better adjustment to both positive and negative cues in their social environment, a stronger cultural imperative among Japanese than Americans.

Mechanisms Linking Emotions and Health

As noted above there is accumulating evidence that emotions are significantly related to health and indications that emotional states may play a detrimental or a protective role. How can these relationships be explained? What are the mechanisms linking emotions and health? The answers to these questions are still emerging but a number of plausible hypotheses have been proposed. These hypotheses relate to both indirect and direct effects that emotions may have on disease processes.

Indirect Links between Emotions and Health: The Health Behavior Connection

One possibility is that emotions influence health indirectly through their effects on behavior, particularly health behaviors. Numerous studies have noted that stress, which often includes emotional upset, is associated with poorer health behaviors. For example, higher levels of stress have been associated with higher levels of smoking as well as increased alcohol and drug usage and poorer eating habits. Specific emotions also appear to be associated with health behaviors. For example, there is evidence that higher levels of hostility are associated with greater consumption of cigarettes and alcohol as well as less physical exercise and poorer self-care (Smith, 1992). Another example concerns the link demonstrated between negative affect and treatment nonadherence in the case of HIV (Gonzales et al., 2011). Supportive evidence for this possible link also comes from research investigating pathways between positive emotions and health demonstrating that positive emotion is associated with greater health-enhancing behavior such as better diet and regular exercise (Pressman and Cohen, 2005; Steptoe et al., 2009).

Direct Links between Emotions and Health: The Physiological Connection

There also appear to be direct physiological links between emotions and health. In addition to their experiential aspects

emotions are very much physiological events. There has been much controversy over the years about the precise relationship of emotions to physiology, whether there are specific patterns of physiological changes that correspond to specific emotions, and whether the phenomenological experience of emotion precedes or is the result of such physiological changes, but there is no doubt that emotions are associated with a variety of physiological changes. These changes occur in a number of different bodily systems including the nervous, cardiovascular, respiratory, endocrine, and muscular systems and vary considerably in intensity. A substantial number of studies have attempted to chart these changes and relate them to specific emotions. Results from such studies have been mixed in that physiological changes found for specific emotions tend to vary considerably between studies and with the methods used for evoking emotion as well as measuring physiological changes. In many respects, this variation is not surprising given the complexity of physiological events and the methodological hurdles in establishing their relationship to particular emotions. Although there is considerable controversy about the precise relationship between emotions and physiology, progress has been made in charting likely physiological pathways between emotions and specific diseases. Some of the most first evidence came from work on the relationship of anger and hostility to cardiovascular disease. A number of studies have found that individuals high in anger and hostility tend to show heightened physiological, and particularly cardiovascular, responses to various stressors. Although results have not been entirely consistent, there is evidence that individuals who are high in hostility, and who are thus more prone to the experience of anger, show larger stress-related increases in blood pressure, heart rate, and stress-related hormones than do individuals lower in hostility. This heightened physiological reactivity appears particularly likely when the person is faced with social stressors such as harassment or other social challenge and is considered by some to be at least a marker if not a causal agent for the future development of cardiovascular disease (Smith, 1992). Recently, the focus of emotion research has shifted from researching general physiological indicators of activation to affective neuroscience (Davidson et al., 2000).

In addition to heightened reactivity in the face of stressors, it is also quite possible that high hostile individuals experience more situations evoking anger, either because they gravitate toward such situations and/or because their actions tend to evoke hostile responses from others. For example, there is evidence that high levels of hostility are associated with generally high levels of interpersonal conflict and low levels of social support. In addition, high hostility has been associated with the experience of more frequent and severe daily hassles as well as major negative life events. This tends to suggest a synergism between poor interpersonal relationships and high physiological reactivity, which would further increase the high hostile individual's vulnerability to disease (Smith, 1992).

Another important link concerns the relationship of emotion to immune functioning. In this respect, there is a growing literature showing that the tendency to experience certain emotions can affect immunocompetence, as can transient moods. First, indices of immunocompetence have been found to be lower among individuals with depressive symptomotology as well as among recently bereaved individuals who strongly suggest that dysphoric moods may lead to the suppression of immune functioning (Kiecolt-Glaser et al., 2002). One possible explanation for this is that withdrawal responses and the generally more passive coping responses associated with helplessness and depression are associated with the activation of the hypothalamic–pituitary–cortical axis, which leads to increases in cortisol output, which in turn have the effect of suppressing immune functioning. Such processes have important implications for a variety of immune-related diseases including cancer, AIDS, and autoimmune diseases. Recently, inflammation has been identified as a crucial immunological process linking negative affective states and a variety of physical health risks such as cardiovascular disease. There is evidence that adaptive emotion regulation is associated with lower and accordingly maladaptive emotion regulation with higher levels of inflammation markers (Appleton et al., 2013).

There is also growing evidence showing that changes in physiological systems represent a pathway between positive emotion and health in adulthood (Ong, 2010). For example, trait positive emotion is associated with lower salivary cortisol output, lower ambulatory heart rate, and reduced fibrinogen responses (Steptoe et al., 2005). Finally, there is increasing support for the suppression and expression of emotion having both physiological and immunological effects. Inhibition of emotion has been shown to lead to changes in electrodermal as well as cardiovascular activity. Also, in addition to evidence cited above demonstrating that suppression of negative emotions is related to reduced immune functioning, there is evidence from a growing number of studies that the expression of negative feelings as a form of catharsis can result in improved immune functioning. For example, several studies have now demonstrated that having people write or talk about traumatic experiences they have not disclosed to other people previously results in an increase in immune responsiveness (Pennebaker and Chung, 2011).

Recent comparative research has put to test the assumption that previously observed physiological pathways might be universal. Examining the link between negative emotions and proinflammatory markers (specifically interleukin-6, IL-6) among Americans and Japanese, Miyamoto et al. (2013) have shown that, as expected, the negative emotions predicted higher IL-6 among Americans, whereas such a prediction was absent among Japanese for whom the experience of negative emotions are seen as more acceptable (and sometime expected) than for Americans (Eid and Diener, 2001; Uchida and Kitayama, 2009). This pattern remained after controlling for a wide range of demographic, psychological, and health-related variables.

Common Underlying Factors between Emotions and Health: Constitutional Vulnerability

A third possible link between emotions and health is that there may be common underlying factors for both emotionality and the occurrence of disease. For example, there may be genetic factors that influence, on the one hand, the emotions a person experiences and how those emotions are expressed and, on the other hand, the occurrence of ill health in general as well as specific disease conditions. For example, recently a common underlying genetic mechanism of inflammation and depressed

mood as a behavioral manifestation has been suggested (Raison et al., 2006).

Reducing Health Risk

The emerging pattern of linkages between emotions and health raises the question of what can be done to reduce the health risk from negative emotions and boost the benefits from positive ones. Three possibilities are considered here but these are best seen as only representative of interventions that may be effective. First, psychotherapeutic techniques can be used to help people deal more effectively with negative emotions as well as boost positive emotions; replacing maladaptive emotion regulation strategies by more adaptive ones is the goal of many recent intervention approaches (Gross, 2014). Numerous techniques have been developed, and there is reason to believe that at least some of these may have positive benefits for physical health as well as mental health. For example, psychotherapy interventions have been shown to be effective in boosting immune responsiveness and improving physical health. Recently, psychotherapy with cardiac patients has been shown to lead to better outcomes (Ladapo et al., 2012), which is consistent with data showing that psychotherapy with a variety of medically ill patients can lead to improved health outcomes (Fawzy and Fawzy, 1994). Of course, psychotherapy does more than simply reduce dysfunctional negative emotions and boost positive ones but such data, in conjunction with the evidence on the role of emotions in health, suggest the potential of psychotherapy for reducing the negative effects of emotions on health.

Closely related to these effects of psychotherapy in general is work showing the psychological and physical benefits of writing or talking about traumatic events. Research by Pennebaker and others has produced substantial evidence for the positive psychological and physical benefits of writing as well as talking about traumatic events. Overall, when people, ranging from university students to holocaust survivors, are induced to write or talk about traumatic experiences positive psychological benefits are found and there are reductions in harmful arousal as well as improvements in immune functioning and subsequent reductions in the number of times the person seeks medical attention. Such changes are particularly evident when the person writes or talks about traumas that had not been previously disclosed to others and when he or she writes about the emotions involved and not just the facts of the situation (Pennebaker and Chung, 2011). This strongly argues for the health benefits of disclosure of negative experiences to others and suggests an apparently powerful way of reducing the harmful effects of emotion on health. It has to be noted that a series of individual, social, and cultural factors may moderate this link between expression of emotions and physical health (Consedine et al., 2002).

Finally, evidence on the role of anger and hostility in heart disease strongly argues for interventions directed toward reducing these potentially harmful emotions. A number of strategies have been suggested and there is evidence that teaching people to be aware of their feelings and then utilizing a series of strategies for dealing with difficult life situations can have positive effects both on the person's relationships and psychological adjustment and possibly on their physical health as well (Suls, 2013).

Implications and Future Directions

Findings concerning the relationships of emotion to health are a prime example of the way in which psychological, social, and cultural factors are closely intertwined with biological processes in determining one's health status. Disease is clearly a biological phenomenon but it is one that is strongly influenced by psychosocial and cultural factors. Also, phenomena such as emotions that are generally viewed in the realm of the psychological have a definite basis in biological processes. As such one cannot speak of psychological processes without consideration of the biological and vice versa.

Although the evidence relating emotions to health has been growing rapidly, there are still many questions that remain to be answered. One major question concerns the degree to which specific emotions are related to specific disease conditions. There has long been speculation about such relationships but as yet there has been no clear resolution of this question. Whereas work on such topics as negative affectivity tends to suggest a general relationship between negative emotions and ill health, other work tends to suggest at least a degree of specificity. This is a question that needs further work and one which will benefit from a clearer specification of how one can best differentiate between different emotions both psychologically and physiologically. Relatedly, there are still many questions about the mechanisms linking emotions and health. Evidence for the roles of physiological reactivity and immunocompetence in this linkage is growing but much remains to be learned. Exactly how is it that different emotions produce these physiological changes? What other biological processes operate in linking emotion to health? How are genetic factors involved in this relationship? A growing, but still limited area of research is the role of cultural factors in the emotion–health link. Evidence from diverse regions of the world with different physical, religious, economic, and interpersonal environments is desperately needed to reach a more generalizable body of knowledge. Finally, much remains to be done with respect to capitalizing on what has been learned in this area for improving health. Current interventions have been described but these would appear to only scratch the surface of what might be possible with respect to harnessing psychological methods for improving physical health.

Emotions and Intergroup Relations

Colin W Leach, Fouad Bou Zeineddine, and Atilla Cidam, University of Connecticut, Storrs, CT, USA

Abstract

Emotion has long been considered important to the relations between groups because emotions are powerful collective experiences that people share with like-minded others. As such, emotion enables coordinated and concerted action as a group, vis a vis other groups. As such, the emotions that people feel about intergroup relations are useful to social and behavioral science because they are potent symbols for the meaning people give to their experience. In this article, we focus on recent social psychological work on anger, empathy, pride, shame, and guilt.

The (social, political, economic) relations between groups have long been considered passionate affairs. Since antiquity, observers have focused on pride in one's nation, hate for one's enemies, and shame for the foibles of one's fraternity. Because emotions were long considered irrational and impulsive states, a great deal of classical thought viewed emotion suspiciously as a tempest in the otherwise tranquil sea of social life. This view of emotion continued in much of early twentieth-century social scientific work on antagonistic social relations evidenced in crowds, war, protest, revolution, prejudice, caste, and conflict. For example, in much of the psychological work on stereotypes, prejudice, and discrimination before the 1960s, feelings of indignation, disgust, envy, and even hatred were thought to provide the psychological animus behind the oppression of societally devalued or disadvantaged groups. Influenced by psychoanalytic notions that destructive feelings and impulses submerged below the surface were the primary drivers of intergroup antagonism, many social and behavioral scholars viewed groups as something like Freud's primal horde blinded by their bloodlust and rapacious desire for power (for reviews, see Duckitt, 1992; Mackie and Smith, 2002). Even the seemingly benevolent feeling of love and pride for one's own group was refracted into a latent ethnocentrism that positioned own as superior and other as inferior when viewed through the prevailing lens.

Parallel developments in approaches to emotion and intergroup relations in the 1960s ushered in a radically different view, however. At the same time as cognitive, phenomenological, and semiotic (or meaning-based) approaches to emotion began to replace psychodynamic notions, sociological and psychological approaches to intergroup relations began to increasingly understand emotion as a marker of the social and psychological quality of the actively constructed relations between groups. Nowhere is this convergence of ideas more clear than in the sociological and psychological work on the concept of relative deprivation in the 1960s and 1970s. Much of this work was an attempt to understand the social, political, and economical bases of the feelings of anger and resentment expressed by people around the world disenfranchised by colonialism, poverty, segregation, sexism, and other large-scale forces that promote inequality between groups (for a review, see Walker and Smith, 2002). What sociologists, psychologists, and economists came to see is that the anger in the streets, in Jakarta, in Watts, in Algiers, in Paris, was not the spitting, envious, infantile, and irrational anger of the mob described by thinkers such as Freud, Le Bon, or Tarde. Rather, the anger in the streets, in the music, and in the posture of the people, was an anger of resistance. And, the action of this anger was often calculated, targeted, and the result of organized efforts to rebel. Although many everyday accounts, and some scholarly ones, continue to describe collective rebellion as 'riots' of rage and 'mob mentality,' this view of emotion in intergroup relations is increasingly regarded as misguided (van Zomeren et al., 2012; Walker and Smith, 2002; see also Scott, 1977).

Anger in Intergroup Relations

At the heart of the revolution in thinking about group-based emotion and its role in rebellion was the idea that individuals can feel anger, resentment, and dissatisfaction about grievances that they share with other members of their in-group. This is called (a sense of) relative deprivation (for a review, see Walker and Smith, 2002). And, this shared anger is a basis for shared action to coordinate in-group members to rebel against those viewed as responsible for illegitimate deprivation. In fact, a comprehensive empirical summary by Smith and Ortiz (2002) showed peoples' feelings of group deprivation to be a potent predictor of the desire to protest, as well as actual protest. In contrast, feeling dissatisfied about individual grievances has little link to protest, instead predicting psychological difficulties such as stress and poor well-being. Recent integrative work on relative deprivation in sociology and social psychology shows that this form of anger can operate in conjunction with quite careful consideration of the material and other resources at one's disposal and with deliberative estimations of the effectiveness of various strategies of protest. Thus, rather than being an irrational and impulsive basis of destructive antagonism, anger about a group grievance is often part of a larger constellation of feelings, thoughts, and motivations aimed at best addressing the grievance (van Zomeren et al., 2012). A growing body of research on anger in intergroup relations more generally also shows that anger is a common response to a sense of grievance and that it routinely motivates people to resist, rebel, or otherwise take antagonistic action aimed at redressing a perceived wrong (for reviews, see Mackie and Smith, 2002; Parkinson et al., 2005). This is consistent with appraisal theories of emotion, which argue that

 http://dx.doi.org/10.1016/B978-0-08-097086-8.24057-9

the emotion of anger is based in part on appraisals (or interpretations) of an unpleasant event as a wrong that should be righted by some form of antagonistic action toward those responsible (see Lazarus, 1991).

Although the experience of anger may be seen as implying that one has some modicum of power or control to act (Lazarus, 1991), the calculus of how to act most effectively appears to be a distinguishable process (van Zomeren et al., 2012). In fact, impulsive or otherwise poorly planned resistance can undermine the apparent purpose of anger by leading people to engage in unwise or ineffective action. Combining anger with strategic concerns for the efficacy of possible action may be especially important in intergroup relations marked by dramatic differences in power, status, and moral commitment. Like in all relationships, in intergroup relationships the aggrieved party must gauge what can and should be done with its anger. This determination should be based in its assessment of the solidarity of feeling in the group and its ability to act in the concerted and coordinated way required for effective protest (van Zomeren et al., 2012). Of course, even the most organized group must also strategize in response to the coordination, power, status, and likely response of its adversary. Thus, it is important to be aware that emotions such as anger do not necessarily lead to antagonistic action irrespective of the quality of the intergroup relation in which the anger develops. Emotions are, after all, relational. As emotions emerge within relationship their expression in feeling and action also emerges within the relationship and is thus rooted in it (Lazarus, 1991; Tiedens and Leach, 2004). A group of workers, aggrieved at a cut in pay, is likely to express and act on its anger in the context of a cooperative relationship with benevolent management in a way quite different to another in a competitive relationship with blatantly exploitative or callous management. Anger in a cooperative or otherwise benevolent relationship is more likely to manifest as a complaint oriented toward constructive efforts at changing the other party or the relationship itself for the better. In contrast, anger in a competitive or otherwise malevolent relationship is more likely to be a protest oriented toward destructive efforts at punishing the other party, weakening their ability to do further wrong, or reducing the material or psychological importance of the relationship itself (for discussions, see Parkinson et al., 2005; Tiedens and Leach, 2004).

Other Examples of Emotions in Intergroup Relations

Although work on anger and relative deprivation in intergroup relations continues, social psychological work in the last 15 years has come to focus on a wider range of emotions in a wider range of intergroup relations than the gross inequality typically studied in work on relative deprivation (for reviews, see Mackie and Smith, 2002; Parkinson et al., 2005; Tiedens and Leach, 2004). This recent effort was aided by Smith's (1993) important ideas integrating the social psychology of group identity, emotion, and intergroup relations. Since then, social psychologists have developed emotion-based approaches to relative group advantage (Leach et al., 2002), stereotypes (Fiske et al., 2002), prejudice (Cottrell and Neuberg, 2005), and a host of other phenomena that occur within intergroup relations (for reviews, see Iyer and Leach, 2008; Mackie and Smith, 2002; Parkinson et al., 2005).

Empathy

In many ways, empathy is the most general way in which we can understand how the relations between parties affect them emotionally. Indeed, empathy appears to be the psychological process by which the boundaries between people are transcended to increase understanding and responsiveness. A prominent view in social psychology is that there are different kinds of empathy. Three types are most often discussed: perspective-taking, empathic concern (i.e., sympathy, compassion), and empathic distress (Davis, 1983). However, empathy can also be thought of simply as the ability to simulate, or mirror, the cognitive, motivational, affective, and/or behavioral state of another organism (Iacoboni, 2009). Both perspectives seem valid. According to the ethologist De Waal (2008), empathy and imitation share a hard-wired simulation mechanism observable in humans and many other social organisms. This mechanism allows for simple and effortless types of empathy such as emotional contagion, mirroring, and motor mimicry. But, as cognitive capacities increased over evolutionary history, this state-matching became more complex among social species to include more elaborate forms of empathy (e.g., concern for other and perspective-taking) and imitation (e.g., coordination, shared goals, emulation).

Many empathy researchers are concerned with the question of how empathy translates into altruism and prosocial behavior. De Waal's (2008) examination of the evolution of empathy argues that the adaptiveness of empathy is determined by the degree of self–other differentiation, trust in reciprocity, and the value given reciprocal altruism. Thus, where self and other are highly differentiated – perhaps because of tribal, ethnic, national, or other group distinctions – there is likely to be less empathy. Less empathy is also expected in structural, political, and cultural contexts where reciprocity is not prioritized or is not possible. Consistent with this view of empathy as rooted in social relations, psychological research has shown that empathy is less likely when others are not valued (Batson et al., 2007), and when others are seen as unfair (Singer et al., 2006).

Self–other distinctions in power are also associated with lower empathy. For example, powerful people engage less in perspective-taking (Galinsky et al., 2006), and show less empathic concern and more egocentric allocation than the less powerful (Dana et al., 2007). Where 'market' exchange relations and competitiveness are inherent 'rules,' the less powerful are seen as responsible for their own advancement. Thus, the less powerful are 'fair game' for the more powerful to exploit without concern for their welfare. Importantly, many of these trends can be eliminated by changing the rules of the game to espouse reciprocity (van der Weele et al., 2010). And inducing empathy can also eliminate the egocentrism that the powerful display in a 'business transaction' environment (Batson and Moran, 1999). However, in such environments the *completely* powerless are not seen as viable competitors for resources nor as responsible for their own advancement. This evokes among the powerful feelings of social responsibility and altruistic

behavior instead of competitive dominance and egocentric behavior (Handgraaf et al., 2008).

Although much of the above work focuses on individuals' empathy toward other individuals, it is clear that similar processes occur in the empathy that individuals experience toward members of out-groups (for a review, see Weiner, 1995). For example, Fong (2007) found that poor people, who are seen as having *some* power and as responsible for their poverty, invite less empathy and help from others. Similarly, empathy for groups victimized by war or oppression is increased by valuing the group and by not seeing the group as responsible for its own suffering (e.g., Cehajic et al., 2009). At an even simpler level, intergroup distinctions between self and other affect the level of empathy that people experience. Thus, whether in the majority or the minority, ethnic groups show greater empathic neural responses to in-group than to out-group members (for a review, see Chiao and Mathur, 2010).

Although people appear to be especially empathetic to fellow in-group members, this too appears to be modulated by power and status. In fact, members of low power or otherwise subordinate groups show an even greater bias in favor of empathizing with in-group members than do members of dominant groups (Chiao and Mathur, 2010). Consistent with De Waal's (2008) more general view, this is likely the result of the lesser value and trust given to intergroup reciprocity by subordinate groups, who have more reason to wary of reciprocity in unequal intergroup relations. Indeed, members of subordinate groups distrust dominant groups and authorities more than do others, often with good reason (for a review, see Bou Zeineddine and Pratto, 2014). Especially for subordinate groups then, being more empathic toward the in-group than the dominant out-group reduces the individual costs and risks associated with nonreciprocated empathy and altruism. In contrast, for powerful or dominant groups, there is little cost, little risk (and little value) in empathizing with the less powerful even if they are unlikely to reciprocate (see also Leach et al., 2002). The greater prevalence of opportunity-hoarding, dominance, and exploitation among advantaged groups who have overcome the problem of subsistence has strengthened their orientation toward competition and profit (see Scott, 1977). When combined with recent shifts toward greater individualism and narcissism, such dominance may be expected to reduce empathy (see Konrath et al., 2011).

The literature on empathy also shows many ways in which empathy can be used to improve intergroup relations. In their review, Batson and Ahmad (2009) identify perspective-taking as especially promising in reducing stereotyping, increasing situational explanations of suffering, and fostering positive attitudes, empathic concern, and willingness to help out-groups. Because of this, many interventions aim to improve intergroup relations by inducing or encouraging empathy for the disadvantaged. For example, the encouragement of empathy is used in conflict resolution and reconciliation workshops and antidiscrimination and bullying educational programs. In many of these interventions, personalizing contact with individual members of disadvantaged groups, sympathy-provoking examples, and/or the identification of common goals initiate perspective-taking. Perspective-taking, and the associated situational explanations of suffering, generate empathic concern for the out-group member. Concern for the out-group member translates to concern for the out-group as a whole. It is unclear, however, how such efforts at using empathy to reduce prejudice and improve understanding might translate into larger scale change at the cultural, political, or structural level. There is a danger that the effects of empathy interventions remain psychological and local, never translating to the core aspects of the intergroup relation that are likely to have reduced empathy in the first place. Future work would do well to better integrate the macro- and microelements of empathy so that this important concept can be better used to examine and improve intergroup relations.

Pride and Other Positive Emotions

Likely because unpleasant emotions are considered more common or more important in intergroup relations, there is decidedly less work on pleasant feelings, such as pride, joy, and satisfaction (for reviews, see Iyer and Leach, 2008; Parkinson et al., 2005). This parallels work on emotion more generally, which also tends to parse unpleasant emotions more finely and to thereby focus on a larger variety of unpleasant emotions (see Lazarus, 1991; Tiedens and Leach, 2004). Often, when pleasant emotions are examined, they are taken to be problematic for intergroup relations. For example, some recent studies examine Schadenfreude – satisfaction at seeing an out-group suffer a defeat or other misfortune. Gloating over the inferiority of out-groups is another emotion that is implied in work on expressions of in-group superiority, nationalism, collective narcissism, and the excessive glorification of the in-group (for a discussion, see Leach et al., 2002). This has some similarity to notions of individual narcissism and hubristic pride, as such positive feelings are thought to be exaggerated and unnecessarily antagonistic (Tracy et al., 2007).

There is surprisingly little work on the seemingly more prevalent and pervasive feeling of pride that people feel about their national, ethnic, political, and other in-group memberships (for a review, see Leach et al., 2002). However, the experience of pride is often implied in a lot of theory and research on the experience and expression of positive in-group identity. Whether higher or lower in power and status, in-groups that afford positive identification are presumed to lead individuals to feel proud of their membership in the group. Such pride is expected to lead members to view the group and its future more optimistically and it is expected to lead members to be more committed to the group and be more willing to sacrifice for the group's benefit. However, more work is needed to determine whether, when, and why pride in one's in-group is related to the perceived in-group superiority and hostility toward out-groups that are more obviously troublesome for intergroup relations.

Shame and Guilt

In an effort to understand perpetrator groups' acknowledgment of their mistreatment of out-groups and their possible role in processes of restitution and reconciliation, researchers have recently focused on self-critical emotions about in-group wrongdoing like shame and guilt (for reviews, see Branscombe and Doosje, 2004; Iyer and Leach, 2008; Parkinson et al., 2005). Although the words 'shame' and 'guilt' are often used

interchangeably in everyday English, they are typically conceptualized as two distinct emotions that have distinct implications for intergroup relations in light of group wrongdoing. The prevalent view in emotion theory and research is that guilt is a feeling of regret and blameworthiness for causing another party harm. As such, guilt is thought to be linked to empathy for the other's suffering and thus a desire to make restitution for it (e.g., apology, compensation). Shame is thought to be a more intense and aversive state of self-criticism focused on the perpetrator's flaw rather than the harm caused the victim. Thus, shame is thought to be less moral than guilt, motivating perpetrators to avoid their misdeeds and those harmed by them (Tracy et al., 2007).

There is now ample evidence that individuals can feel shame and guilt about the wrongdoing of their group (for reviews, see Branscombe and Doosje, 2004; Parkinson et al., 2005). Like most other such group-based emotions, shame and guilt are greater when individuals feel psychologically connected to their in-group and recognize its role in wrongdoing against undeserving victims (for a review, see Iyer and Leach, 2008). For example, Iyer et al. (2007) found students in the US and the UK to report feeling a little guilty and a little more ashamed about their country's occupation of Iraq and its detrimental effects on the citizenry. Both feelings were associated with holding the in-group responsible and viewing its actions as illegitimate. Consistent with this, both shame and guilt predicted a greater desire to see the US and the UK withdraw from Iraq and to compensate Iraqis for the damage done. Although anger was most associated with wanting to confront the respective governments for the wrongdoing, shame and guilt were also associated with this sort of antagonistic political action. These findings are consistent with a great deal of other work showing that individuals' guilt about an in-group's wrongdoing is tied to wanting to make up for the wrongdoing, typically by apologizing or compensating (for a review, see Branscombe and Doosje, 2004). Although the positive effects of shame in Iyer et al. (2007) run in contrast to the general view of this emotion as oriented to the avoidance of wrongdoing, numerous recent studies also show shame to be linked to the constructive approach of in-group misdeeds (for a review, see Gausel and Leach, 2011).

One reason that shame may be linked to wanting to make restitution for in-group wrongdoing is that the feeling of shame can be based in a concern for the in-group's image in the eyes of others. In fact, in Iyer et al. (2007), participants' shame was linked to a concern that the country's social image in the eyes of others was threatened by their occupation of Iraq. One way to reduce this threat to social image is to make restitution to the out-group in an attempt to reestablish the in-group's moral standing (for a review, see Gausel and Leach, 2011). Many countries, for example, make material or symbolic restitution to out-groups they have mistreated in an effort to regain acceptance in 'the international community' after being condemned by them. Indeed, membership in international organizations, such as the United Nations or the European Union, is sometimes predicated on aspirants atoning for past wrongs. The European Union pushing Turkey to acknowledge the mass killing of Armenians in the early twentieth century is only one example of this.

Shame about in-group wrongdoing can also be linked to support for restitution because group members wish to improve the collective self-image damaged by their wrongdoing (Gausel and Leach, 2011). Because shame is more focused on peoples' identity as good, shame may motivate change of the self in a way that guilt's focus on the harm of wrongdoing may not. Where shame is the result of an intense self-criticism for a failing in the self that can be repaired, shame is likely to lead to concerted effort to improve the self (Gausel and Leach, 2011). By improving the group's failing, shame may offer a more profound change that is more promising for the in-group's relation to the out-group relations and is thus more satisfying to the affected out-group. Of course, where shame is felt about an irreparably damaged social image or self-image, such shame is likely to lead to the kind of avoidance of wrongdoing and those affected by it that emotion theory and research consider detrimental to social relations. Thus, the latest theory and research on shame and guilt about in-group perpetrators of wrongdoing suggest that the reparability or irreparability of the wrongdoing is more important to understanding what group members will do than whether they experience shame or guilt. As feelings of self-criticism, both shame and guilt may motivate constructive efforts when this criticism is aimed at a wrongdoing that is seen as reparable through concerted action. On the other hand, feelings of self-criticism, especially the more intense emotion of shame, may motivate an avoidance designed to defend self-image and social image when it appears that little can be done to redress the in-group's wrongdoing. Taken together, this line of thinking suggests that those who wish to encourage constructive efforts to repair wrongdoing and to reconcile perpetrator and victim would do well to encourage perpetrator and victim to view the wrongdoing and the intergroup relation as reparable.

Conclusion

Emotion has long been considered important to the relations between groups. This is because emotions can be powerful collective experiences that people share with like-minded others. Such shared emotion is a sign of the solidarity that enables coordinate and concerted action as a group, such as in a protest or a parade. Although emotions were frequently considered an irrational and impulsive basis of conflict between groups, it should be clear that emotions are now typically thought of as the social and psychological meaning that individuals give to their membership in a group and to its relation with other groups. As such, the emotions that people feel about intergroup relations are useful to social and behavioral science because they are potent symbols for the meaning people give to their experience (Tiedens and Leach, 2004). To know that a group's members are angry about a court decision is to know that they feel that the decision is unfair and that they may be prepared to act against it. In contrast, to know that the group is sad is to know that they are disappointed about the court decision and that they are unsure if they have the wherewithal to respond. Social and behavioral scientists use emotion terms to describe these experiences for the same reason that the people they study use emotions to characterize their own experience; emotions are pregnant with meaning and

motive. Thus, compassion, pride, joy, shame, anger, envy, disappointment, and the like allow us to convey a great deal about what we think, what we feel, and what we wish to do about the world we live in and those we live with. Poets, priests, and politicians all recognize this power in emotion, and thus work at moving people to common feeling for a common purpose. Those who wish to understand such collective mobilization would do well to examine and understand the social psychological processes at the heart of emotion.

Emotions and Work

Neal M Ashkanasy, University of Queensland Business School, The University of Queensland, Brisbane, QLD, Australia

Abstract

Although neglected until the 1990s, the study of emotions in workplace settings is now recognized as a legitimate and important field of research in industrial and organizational psychology. In this article, I review the field of emotion in the workplace from five perspectives, corresponding to five discrete levels of analysis: (1) within-person temporal effects, (2) between-person (personality and attitudes) factors, (3) interpersonal behaviors (perception and communication of emotion), (4) group level (leadership and teams), and (5) organizational level (culture and climate). Within these perspectives, I address the importance of affective events theory, deal with positive and negative affect (state vs trait), as well as emotional intelligence, labor, and contagion. The article concludes with suggestions for future research.

Introduction

Emotions may be defined as the experience of a form of biological response to environmental stimulus, resulting in physical and psychological changes and subsequent readiness for action (Frijda, 1986). While early scholars of industrial and organizational (IO) psychology and organizational behavior (OB) seemed to recognize the importance of studying emotional dimensions (Brief and Weiss, 2002), post-WWII research tended to concentrate on behavioral and cognitive aspects of work, where emotions and affect were subsumed under the broader heading of job satisfaction (Barsade et al., 2003).

This situation began to change, however, following publication of Hochschild's (1983) sociological analysis of emotional labor, which suggested that employees forced to display emotions at odds with what they truly feel, suffer burnout and loss of productivity. The concept of emotional labor sparked increased interest in emotions and soon found its way into mainstream OB literature (e.g., see Rafaeli and Sutton, 1989). Subsequent seminal reviews by Pekrun and Frese (1992) and Ashforth and Humphrey (1995) served to broaden interest in this field further. Subsequently, publication in 1996 of Weiss and Cropanzano's idea of 'affective events' provided a useful framework for studying emotions in the workplace as a dynamic phenomenon. This period marked "the affective revolution in organizational behavior" (Barsade et al., 2003: p. 3). The ongoing level of interest in studying emotions in organizational settings is today reflected in the existence of an annual book series in this topic, *Research on Emotion in Organizations* and an associated biannual conference, the *International Conference on Emotions and Worklife* (http://www.emotionsnet.org). More recently, Ashkanasy and Humphrey (2011a) provided a comprehensive review of emotions in organizational settings, which forms an appropriate basis for this article.

The Multilevel Model of Emotion in Organizations

Ashkanasy and Humphrey (2011a) based their discussion around an integrated model of emotions in organizations developed by Ashkanasy (2003a). The model crosses five levels of analysis and, as such, provides an appropriate framework to structure this article. At the base of the model, Level 1, are temporal variations in emotions and behavior, referred to as 'within-person' variability. Level 2 refers to between-person variability, such as personality and emotional intelligence. Level 3 refers to interpersonal relationships, including perception and communication of emotion, including emotional labor. At Level 4, analysis shifts to group phenomena including team leadership. Finally, at Level 5 of the model, the focus is on the organization as a whole including emotional culture and climate.

Level 1: Within-Person

Ashkanasy and Humphrey (2011a) point out that "Level 1 is best understood in terms of Affective Events Theory (AET: Weiss and Cropanzano, 1996)" (p. 215) and distinguish between positive and negative mood effects (Ashton-James and Ashkanasy, 2005). In this regard, Isen (1987) and Fredrickson (2001) stress the role of *mild positive affect* as a catalyst of creativity and cognitive flexibility. A further noteworthy aspect of within-person variation is that, under this perspective, empirical procedures need to take account in real time of variations in affect and behavior (Fisher, 2008). Research, for example, can use daily diary data (e.g., see Weiss et al., 1999) or experience sampling methods (ESM: Larson and Csikszentmihalyi, 1983; also known as ecological momentary assessment, Weiss and Beal, 2005), where measurements are taken several times over a day. For example, Amabile et al. (2005) found in an ESM-based field study that (mild) positive affect is related to improved product design and innovation.

Other evidence tells us that negative affect can also lead to increased creativity and innovation under particular circumstances. For example, To et al. (2012) found ESM data to suggest that whether positive or negative mood leads increased creative behavior depends on an interaction of situation and personality. This finding is consistent with the 'sadder but wiser' hypothesis put forward by Staw and Barsade (1993). Forgas and George (2001) point out further that employees in

a negative mood are likely to be less susceptible to bias and less likely to be swayed by persuasion (Forgas and East, 2003).

In workplace settings, where tasks are likely to involve substantive cognitive processing, Forgas and George (2001) argue that employees are likely to be subjected to 'affect infusion' (Forgas, 1995), whereby their affective states color their decision making. In demonstration of this effect, Mittal and Ross (1998) found that risk taking under conditions of uncertainty is higher for decision makers in a positive rather than a negative mood. Ashton-James and Ashkanasy (2008) argue that this is because managers in a positive mood tend to be more optimistic in their situation appraisals than when they are in a negative mood, and therefore are more prone to taking risks. Note, however, that risk taking, especially in today's dynamic business environments is not necessarily a bad thing. For example, risks often need to be taken when the organization needs to move quickly to respond to a changed regulatory or market environment. This effect has subsequently been demonstrated in field research by Amabile et al. (2005).

Researchers have also employed diary methods and ESM to unravel some of the enduring mysteries of job satisfaction. Thus, while job satisfaction has long been thought to be an affective variable, Weiss et al. (1999) used a daily diary method to demonstrate that job satisfaction comprises both affective and cognitive components. Fisher (2002) employed ESM to show moreover that, once (cognitive) attitudinal factors are accounted for, affect is in fact unrelated to job satisfaction. Fisher also demonstrated that affect is related to affective commitment, helping behavior, and role conflict over and above the effects of job satisfaction (see also Fuller et al., 2003). In a more recent ESM study, Fisher et al. (2013) found that momentary emotions depend on task appraisal and confidence.

Another widely accepted misconception about job satisfaction is that it is only weakly related to job performance. For example, Judge et al. (2001) reported the results of a meta-analysis of job satisfaction–performance relationship that the correlation was only 0.30. However, Fisher and Noble (2004), in an extension of Fisher's (2002) earlier ESM studies using programmable watches, found that affect and job satisfaction and performance were strongly related within-person (correlations in the 0.70 range). Thus the within-person relationship is considerably stronger than the between-person job satisfaction–job performance.

In summary of Level 1, it seems safe to conclude that AET and ESM have essentially revolutionized our understanding of the role emotions play in the workplace. AET has been consistently supported across numerous diary and ESM studies (see Weiss and Beal, 2005; for a more extensive review).

Level 2: Between-Person

The dominant variable studied at the between-person (or individual difference) level of analysis is emotional intelligence, which comprises four basic abilities or 'branches': (1) recognition of emotions, both in self and others; (2) use of this information in cognitive decision making; (3) understanding of the effects of emotions; and (4) using and managing emotions in behavioral decision making (Mayer and Salovey, 1997). The construct was popularized by *NY Times* journalist Daniel Goleman (1995), however, resulting in exaggerated claims and led to stringent criticism of emotional intelligence (e.g., see Locke, 2005). On the other hand, Ashkanasy and his colleagues (see Ashkanasy and Daus, 2005; Daus and Ashkanasy, 2005; Jordan et al., 2008) resolutely defended the validity and utility of emotional intelligence, claiming that it is a valid individual difference, similar to cognitive intelligence.

In an effort to clarify the controversy, Ashkanasy and Daus (2005) identified three approaches to emotional intelligence, which they referred to as 'streams.' *Stream 1* is based on the Mayer–Salovey four-branch model and is measured using an IQ-style ability measure called the Mayer–Salovey–Caruso Emotional Intelligence Test (Mayer et al., 2002). *Stream 2* research also uses the Mayer–Salovey definition of emotional intelligence, but is measured using self- or peer-report measures (Brackett and Mayer, 2003). *Stream 3* models of emotional intelligence do not use the Mayer–Salovey definition, and are usually measured using self-reports (e.g., Bar-On, 1997). Ashkanasy and Daus discourage the use of Stream 3 models on the basis that they are usually overly correlated with personality. Nonetheless, in terms of establishing a relationship between emotional intelligence and work performance, Joseph and Newman (2010) and O'Boyle et al. (2011) found in independent meta-analyses that all three streams of emotional intelligence demonstrate incremental validity over and above cognitive ability and personality. More recently, Schlaerth et al. (2013) reported meta-analytic results supporting a positive relationship between all streams of emotional intelligence and skill in conflict resolution.

In summary of the role of emotional intelligence at Level 2 of the Ashkanasy (2003a) model, and despite the controversy, the emerging consensus is that emotional intelligence is an important and valid personality characteristic that is positively associated with work performance.

Level 3: Interpersonal Emotions

This level focuses on how emotions are perceived and communicated between dyadic interactions. In this regard, Ekman (1972) found that emotional expression is a basic human property, independent of race or culture. What is culture specific, however, is the set of rules people employ regarding perception and display of emotions. In this instance, Elfenbein and Ambady (2003) argue that there are strong intercultural differences. Subsequently, Elfenbein et al. (2007) coined the term 'emotional dialect' and used this idea in developing the "Integrated Interpersonal Process Framework for Emotion in Organizations" (Elfenbein, 2007). More recently, Allen et al. (2014) reported finding cross-cultural differences in emotional labor (see below).

As Ashkanasy (2003a) stresses, however, most studies of emotional communication in the context of OB refer to emotional labor. The term was coined by sociologist Arlie Hochschild (1983), who observed that service employees are required as a part of their terms of employment to display appropriate (positive or negative) emotions to customers or clients. For example, service providers in the retail, food, travel,

and entertainment industries are expected to display positive emotional expressions or provide "service with a smile" (Pugh, 2001). Other employees in enforcement industries (e.g., police, debt collection) are expected to display negative emotions.

Hochschild (1983) identified in particular two types of emotional labor. These comprise *surface acting* (outward display of emotion that are at odds with the emotion the actor feels) and *deep acting* (where actors try to experience the emotion). Morris and Feldman (1996) subsequently conceptualized surface and deep acting and their effects in terms of three dimensions: intensity, variety, and duration. In additional to emotional labor, Ashforth and Humphrey (1993) recognized that *genuine* emotions might also be displayed. Diefendorff and Gosserand (2003) subsequently demonstrated empirically that genuine emotion is distinct from emotional labor.

There is also a considerable body of evidence to show that performing emotional labor can have detrimental health effects, especially when associated with 'dissonance' between displayed and felt emotions (Van Dijk and Kirk-Brown, 2006). Moreover, the harmful effects of surface acting appear to be much stronger than for deep acting (Kammeyer-Mueller et al., 2013), even carrying over to home life (Wagner et al., 2014), although Grandey et al. (2012) recently found that the harmful effects of emotional labor are ameliorated in a "climate of authenticity" (p. 1).

On the other side of the service encounter, it appears that deep or genuine emotion is also more effective than surface acting. For example, Groth et al. (2009) found that, compared to surface acting, service provider deep acting resulted in improved customer satisfaction (see also Grandey, 2003).

Level 4: Teams and Leadership

At Level 4 of his model, Ashkanasy (2003a) identified leadership as having a major effect on the moods and feelings of team members. A similar conclusion was reached by Humphrey (2002), who argued the mood management may well be the most critical element of team leadership. This idea is also supported in empirical findings reported by Seong and Choi (2014). If this is so, then it would also follow that a leader's emotional intelligence may be the key. In this regard, George (2000) reasoned that emotionally intelligent leaders engender enthusiasm among team members. This idea was supported in empirical research by Pescosolido (2002), who found that effective leaders tended to perform better than their less effective colleagues when it came to dealing with workplace events that involved strong emotions, and that this contributes to development of stronger team harmony and cohesion.

Although controversial (Antonakis et al., 2009), scholarly evidence is tending increasingly to support the notion that emotional intelligence is related to leadership effectiveness. Thus, in a recent review of 10 years of research into the relationship of emotional intelligence and leader effectiveness, Walter et al. (2011) found overwhelming support across all three 'streams' of emotional intelligence identified in Ashkanasy and Daus (2005).

In groups and teams, the principal mechanism for spreading a particular emotional state via emotional contagion (Hatfield et al., 1992), whereby members of a group are 'infected' by others' emotional states through mimicking other members' facial expressions, body language, and vocal tone. Given the modeling role of leaders, it follows therefore that contagion should be a major mechanism for leaders to transfer emotional states to team members. In this regard, Goleman et al. (2002) argue that the most effective leaders (which they refer to as 'primal' leaders) engender 'emotional synchronization' or resonance with their followers. In essence, followers 'tune in' to their leader and adopt whatever emotional state the leader is modeling. Empirical support for the role of emotional contagion in groups comes from a study conducted among MBA study groups by Barsade (2002), while Sy et al. (2005) found evidence for leader-to-member contagion. More recently, Tee et al. (2013) found that the effect can go the other way: from followers to the leader.

A corollary of this is that, to be effective, leaders need to manage emotional contagion lest it spirals out of control. In this regard, Humphrey (2008: p. 1) argues that leaders need to "lead with emotional labor" (see also Ashkanasy and Humphrey, 2011b) as a means to regulate their own emotional feelings. Thus effective leaders engage in genuine emotional expression or (at least) deep acting to model the emotions suited to a particular situation; this emotion is then likely to be picked up by group members (via contagion) leading to the whole team adopting the (appropriate) emotion (Sy et al., 2005).

In addition to the direct role of emotion in leader group/team situations, it seems that emotions also play a key role in broader models of leadership. Indeed, there is evidence that a key skill of transformational leaders lies in an ability to help followers to deal with negative emotional events. For example, in a study of R&D teams, Pirola-Merlo et al. (2002) found that leaders could boost performance by helping their followers deal with everyday frustrations and negative moods. McColl-Kennedy and Anderson (2002) found similarly that transformational leaders engendered positive emotion leading to optimism, improved performance, and goal attainment (see also Tsai et al., 2009).

Finally, it is worth noting that there may also be a potential 'dark side' to emotional intelligence in the context of leadership. For example, Kilduff et al. (2010) recently suggested that emotional intelligence can be used 'strategically' to manipulate others.

Level 5: The Organizational Level

At Level 5 of his five-level model, Ashkanasy (2003a) considers the role of emotions at the organizational level, and argues the need for organizational managers to work toward a "healthy emotional climate" (Ashkanasy and Daus, 2002). In this regard, Härtel and Ashkanasy (2010) posit that a healthy climate is characterized by positive emotions, created and then sustained across the whole organization.

This brings us to the notion of an organizational emotional climate, defined by de Rivera (1992; see also Yurtsever and de Rivera, 2010) as "an objective group phenomenon that can be

palpably sensed – as when one enters a party or a city and feels an attitude of gaiety or depression, openness or fear" (p. 197). In this sense, emotional climate represents a particular form of organizational climate (Schneider et al., 2010), which deals specifically with the collective mood of organizational members, and their attitudes toward their peers and leaders, as well as the organization as a whole. Note that climate there, although related to organizational culture, is differentiated from culture in that it is not a function of organizational members' beliefs, values, and assumptions (Schein, 2004).

There is, however, some debate as to whether emotional climate is a team (i.e., Level 4) phenomenon, rather than something that exists organization wide (Level 5). For example, Ashkanasy and Nicholson (2003) examined a 'climate of fear' into Australian restaurant chains and found that it varied by subunit within the two organizations. This was in contrast to measures of organizational culture, which they found to vary across (but not within) organizations.

In fact, there is evidence that "Level 5 is qualitatively different from the other levels of the model" (Ashkanasy and Ashton-James, 2005: p. 221) insofar as this level subsumes the five lower levels. In this instance, Level 5 emotions are generated as a result of the accumulation of affective events at Level 1, employees' emotional intelligence abilities at Level 2, which, in turn, impacts their interactions with coworkers, subordinates, supervisors, and clients at Level 3, also affecting group emotion and leadership at Level 4. Consistent with this idea, Dasborough et al. (2009) argue that "a leader's behavior to subordinates (Level 4) is reflected in team-member relationships (Level 3) that in turn reflect on the leader's performance via emotional contagion processes, leading to an organizational management response to the leader (Level 5)" (Ashkanasy and Humphrey, 2011a: p. 219). Finally, it should also be noted that organizational culture is often reflected in organizational policies. From the perspective of emotions, this refers to an organization's policies regarding emotional displays required by employees (i.e., emotional labor, see Beyer and Niño, 2001; Diefendorff and Greguras, 2009; Gosserand and Diefendorff, 2005; Fineman, 2000; Hochschild, 1983; van Maanen and Kunda, 1989; Rafaeli and Sutton, 1987, 1989).

Discussion and Conclusions

Although the role of emotion in organizations was neglected for many years, this state of affairs has changed over the past 20 years, to the point where the study of emotions has become a priority in IO research. Major published reviews of the field by leading authors in the field (e.g., Ashforth and Humphrey, 1995; Ashkanasy and Daus, 2002; Brief and Weiss, 2002; Elfenbein, 2007) suggest that this is an area with "a bright future" (Ashkanasy and Ashton-James, 2005: p. 221).

In this brief overview of the field, I employed Ashkanasy's (2003a) structure that includes five levels: (1) within-person temporal effects, (2) between-person factors, (3) interpersonal behaviors, (4) group and team leadership, and (5) the organization-wide view. I also stressed the interconnectedness of the levels, suggesting in Ashkanasy (2003b) that the 'glue' facilitating this lies in the biological basis of emotion.

Looking forward to the future of research in this field, four issues are noteworthy (Gooty et al., 2009). First, there is a need for scholars to be more consistent in their definitions of basic terms, especially when it comes to differentiating affect, emotion, and mood. Second, scholars have generally restricted their studies to positive and negative affect, rather than addressing the effects of discrete emotions. For example, anger, fear, and sadness are all examples of negative affect, but are associated with different action tendencies (Frijda, 1986). Third, while studies of within-person effects using diary or ESM methods are becoming more prevalent, there continues to be a pressing need for more Level 1 research. Fourth, research on emotions needs to pay more attention to the role played by the context in studies of emotion in organizations. In addition to the foregoing points, Ashkanasy (2009) also call for research in OB, in general, to make more use of multilevel analysis and to take into consideration the neurobiological nature of behavior and emotions.

Abstract

Historians have long considered the role of emotions in the past but the explicit study of past emotions and emotional standards has only been studied since 1980. The main emphasis in this field rests on determining points of change in emotional values, and explaining why they occur and what impact they have on individual behaviors and social institutions. Emotions history interacts strongly with anthropological and sociological study. While major areas of inquiry remain open, important findings have focused on key shifts in emotional standards during the eighteenth century and also during the second quarter of the twentieth century. Exploring the consequences of these changes, not only in personal but also in political life, and embellishing analysis through such additional techniques as comparative study, offer important channels for future research.

While historians have long considered the role of emotions in the past, for example in biographies, the explicit study of past emotions and emotional standards has only been studied since 1980. The main emphasis in this field rests on determining points of change in emotional values, and explaining why they occur and what impact they have on individual behaviors and social institutions. Emotions history interacts strongly with anthropological and sociological study. While major areas of inquiry remain open (particularly in the history of societies other than Western Europe and the USA), important findings have focused on key shifts in emotional standards during the eighteenth century (for example, the rise of new definitions and valuations of love) and also during the second quarter of the twentieth century (in campaigns for a reduction of intensity in such emotions as grief, anger, and even love). Exploring the consequences of these changes, not only in personal but also in political life, and embellishing analysis through such additional techniques as comparative study, offer important channels for future research.

Using the Past for New Understanding

This field of study builds on two assumptions. First, historians of emotion believe that emotion, the response to stimuli that combines physiological reactions and cognitive evaluations, plays a significant role in historical action. In this they differ from some historians who have argued, for example in interpreting rioting, that purely rational calculations underlie behaviors even when there are admitted emotional overtones such as anger or fear. Second, historians of emotion believe, and demonstrate, that emotions are subject to change, according to shifts in historical context. In this they differ from some researchers who argue that emotions are human constants, based on inherent biological and psychological factors, varying only by personality. Historians of emotion join anthropologists and many sociologists in seeing emotional standards and reactions as group variables, at least in part. Whereas anthropologists mainly study different emotional configurations across contemporary cultures, historians of emotion deal with changes over time, venturing a periodization of key developments. Historians of emotion also contribute to emotions-study, a concern for the social results of emotional standards, as opposed to purely personal qualities.

Major Themes

Historical research has become a significant contributor to the exploration of emotion and the role of emotion in larger social interactions. Although there are a number of different approaches to emotions history, and several different rationales, most historians agree in the focus on 'changes' in emotional standards and experience. They seek to chart what the changes were, granting that explicit standards, or what is often called emotional culture or emotionology, are easier to delineate than actual individual or collective experience. However, they demonstrate that standards themselves have important results both in emotional life and in social and institutional behavior. Here, indeed, is one of the chief methodological pillars of the field. Historians also try to explain what the 'causes' of change were, which helps connect emotions to larger social developments. They are also eager to show what the 'results' were, not just in individual perceptions of emotions and capacities for display, but in other institutions and interactions.

How the Field Became Explicit

History cannot be written without dealing with emotional issues and expressions. Even before the rise of psychohistory – the application of psychological theories, particularly Freudian psychoanalytic concepts, to historical data – biographers often referred to emotional qualities of their subjects. Classic attempts to convey the larger spirit of a historical period, like Johan Huizinga's characterization of the waning Middle Ages, often included emotional dynamics, as did descriptions of reactions to wars or crowd behavior. With all this, however, the principal focus was not on emotion per se, but on emotion as a component of some other phenomenon.

The history of emotions received a considerable boost in the 1930s. The rise of social history in France, seeking to understand the experience of ordinary people in the past, involved exploring topics not previously part of the historical repertoire. Innovators like Lucien Febvre (1973) specifically called for research on emotions as part of the larger social history effort. At about the same time, German sociologist Norbert Elias sketched his theory of a 'civilizing process,' (Elias, 1978, 1982) arguing that standards of self-control became more rigorous in Europe's upper classes in the seventeenth and eighteenth centuries. His primary focus involved physical behavior, such as eating habits, but his attention to more refined manners also involved discipline over emotion. Neither Febvre nor Elias generated an immediate response; indeed, Elias' theories are used currently more widely than ever before.

The development of psychohistory in the 1970s certainly called new attention to the historical exploration of emotion. Historians of childhood like Philip Greven (1977) and David Hunt (1970) thus explored the emotional impact of characteristic styles of childrearing in the seventeenth and eighteenth centuries, using psychoanalytic theory; Greven focused on the consequences of new styles of discipline associated with religious movements in colonial America. Most psychohistorians, however, concentrated primarily on biography, as in the classic study of Luther by Erik Erikson (1962). Still, historians influenced by Freudianism have continued to contribute, particularly when they have turned to larger cultural standards and individual experience around these standards. Generational emotional results of the experience of World War I have thus figured in some explanations of the rise of German Nazism (including the impact of father absence).

However, most explicit attention to emotions history resulted from a slightly different set of developments, in social history and related social sciences, as a framework established in the 1970s translated into explicit research from the mid-1980s onward. Social historians, now dominant in many areas of historical research, continued to widen their exploration of how ordinary people functioned in the past. A major extension of these inquiries, launched in France but spreading more widely, argued for inquiry into deeply held values and assumptions – *mentalités* – concerning subjects such as death, community, or the forces of nature. Not surprisingly, attitudes about emotion quickly figured into this mix; sweeping studies of fear were one key result. English and American historians, for their part, broadened the investigation of family patterns into qualitative relationships among family members. In this vein they explored shifts in the definition and valuation of love, both marital and parental, and also changes in the ways anger was viewed in family life. Mentalities and family historians alike painted a distinctive picture of emotional standards in early modern – sixteenth to seventeenth century – European and American societies, compared to more modern norms. They also paid explicit attention to processes of change, particularly by the eighteenth century.

Two related strands of social history inquiry thus produced a new understanding of the extent to which past culture, and institutions like the peasant village or the family, could not be grasped without assessing the emotional dynamics involved. The same inquiry underlined the extent to which emotional dynamics varied over time – with the historical period – and were therefore subject to explainable change.

Concurrently, various social scientists exploring emotion, began to probe the historical record as well, in this case with primary, though not exclusive, attention to more recent developments. American sociologists and social psychologists began to look at new emotional standards at work, as service sector jobs expanded in the twentieth century. They also investigated changing definitions of family related emotion. While most anthropologists concentrated on painting rich, but fairly static pictures of emotional standards in various societies, some began to build in attention to change. Thus Robert Levy, in his classic study of the Tahitians (1973), dealt with the impact of Western colonialism on Tahitian emotional culture, while Catherine Lutz (1988) in a variety of studies looked at shifts in emotion over time, while relying heavily on contemporary field work descriptions for her basic categories. A number of European sociologists, some strongly influenced by Elias' theories, began to examine changes in 'emotion management,' particularly in the twentieth century but in some cases over a longer sweep of time, focusing on ways emotional impulses were to be controlled. A Dutch group, in particular, worked on the emotional standards that accompanied more informal manners and relationships in the twentieth century. By the 1980s, explicit work in the history of emotion was well underway (see Wouters, 1992).

Gains and Gaps in Historical Research on Emotion

Once launched, emotions history inevitably gained additional vantage points and emphases. The list of emotions historically explored now includes envy, disgust, joy (tentatively), grief, shame, and guilt, as well as the initial roster.

The takeoff of emotions history has also widened in terms of place and time – crucial indications of a project's significance in this empirically specific discipline. Thus several studies deal with changes and continuities in emotional standards and expressions in Chinese history. Historians addressing medieval Europe have generated an impressive literature, as in an important set of studies on anger and projects on wonder and empathy (Rosenwein, 1998). Classicists are also dealing with love, in the context of further explorations of family history. The growing range still begs for expansion and connection. Changes within the Middle Ages need more explicit linkage to the patterns noted in the early modern centuries, while the Renaissance, as a possible period in emotions history, has not clearly surfaced at all. Geographical gaps are at least as obvious as the challenges in chronology and linkage. Specialists dealing with a number of key areas – Eastern Europe, Africa, Latin America, additional parts of Asia – have yet to generate focused histories of emotion, as opposed to more haphazard overlaps and connections with other topics like family life. Relatedly, key theories about emotional change – such as the civilizing process idea – have yet to be seriously tested beyond the Western context, so despite some speculation there is no consensus about possible applicability. Nevertheless, it is fair to say that the process of moving emotions history toward a full historical canvas is underway.

Two Turning Points

The most elaborate work, however, continues to emphasize developments in the USA and Western Europe. Here, in addition to broadening the varieties of emotions considered and the contexts in which they operate, historians and kindred social scientists have particularly emphasized two points of particularly revealing transformation. An important set of changes redefined emotional culture between the late seventeenth and early nineteenth centuries, with timing somewhat varying with the emotional configuration involved. A subsequent turning point intervened in the second quarter of the twentieth century, possibly a bit earlier in the USA than in Western Europe. Within this periodization framework a host of questions remain disputed or unanswered, but the framework itself has proved widely useful in explaining significant recasting of emotional guidelines and experience, and in beginning to amass evidence about why emotions change and with what larger results.

In the early modern emotionological transformation, two factors propelled change. First, growing commercialization helped place new value on the family, as communities became somewhat more competitive. Family ties were alternatives to older, now frayed communitarian bonds. Same-sex friendships, by the same token, declined. Along with this, Protestantism, attacking the idea of special credit for celibacy, greatly improved the religious status of marriage (and, in destroying convents, made marriage more essential for women). By the seventeenth century, Protestant writers urged emotional sharing in marriage. From these twin bases, actual emphasis on love as a key ingredient in forming and evaluating marriage measurably expanded by the mid-eighteenth century. A concomitant, noteworthy by this point, was a more systematic attack on anger in the family, as contradictory to love and also to the greater equality in human relationships being promoted by Enlightenment ideology. Jealousy was also redefined and more systematically reproached, particularly as the idea of a jealous defense of honor came under attack as uncivilized. Growing emphasis on parent–child love, combined with further erosion of community controls, helped generate the growing reliance on guilt over shame in childrearing (Stearns and Stearns, 1988). Techniques such as isolation increasingly supplanted both shaming and physical punishments, convincing children that love was temporarily interrupted and could be restored only by sincere repentance – often establishing guilt as a durable emotional enforcer of character standards. Grief, though more fully amplified in the nineteenth century, also followed from a greater emphasis on love, along with new beliefs that deaths should be brought under greater control. The apparatus available to commemorate death changed in order to accommodate growing grief needs (Rosenblatt, 1983).

Emotional change also developed outside the family. The acceptability of sadness and melancholy declined, with people (initially, particularly men) urged to present a cheerful demeanor. More broadly, emotions were increasingly seen as operating under individual control, rather than sweeping through the body as an outgrowth of physical humors. Correspondingly, responsibility for personal emotion management increased. Words like temper began to suggest a type of anger that should be controlled, while outright neologisms, such as tantrums, indicated a childish level of rage that could disqualify an adult from serious consideration (Stearns and Stearns, 1986). The rise of new standards of disgust followed from cultural redefinitions of emanations from the body and from growing social inequality, with disgust used to mark and justify boundary lines between respectable and unrespectable people and situations (Corbin, 1986).

Historians are still working out some of the implications of these changes, in altering the context of family life but also spilling over into wider public arenas. The transformation of criminal justice, shifting from shaming to imprisonment, clearly reflected the new commitment to guilt, for example, along with growing disgust at crowd reactions to public punishments. Ramifications of emotional change could reach into a wide spectrum.

Redirections in emotional culture between 1900 and 1950 were also extensive. Here, the dominant motifs are greater control over intensity plus growing informality in social relationships. Some historians also add an increasing democratization of emotional standards, with fewer systematic social divisions between respectable groups and others. Suspicion of intensity showed in several arenas. Anger, previously approved for men as a motivation for business and professional life (though dangerous in the home), was now more systematically reproved, with new techniques designed to defuse it. Grief was increasingly disallowed. Even more revealing attacks on intensity turned against too much stress on guilt, which might damage children's self-confidence. Maternal love, praised without major qualification in the nineteenth century, now fell victim to extensive criticism because of its overpowering qualities; mothers should keep their affection under tighter bounds. Romantic love, which had evolved toward increasingly idealistic statements in the nineteenth century, seemed excessive as well by contemporary standards; many prescriptive writers urged more limited, realistic emotional connections, while also freeing sexuality from some of the emotional commitment promoted in nineteenth-century advice literature (Seidman, 1991; Stearns, 1994).

The new concern about intensity was no accident, and it had some of the same range of effects noted in the earlier Western transformation. Causes centered on changes in economic structure, and therefore emotional functions, along with the rise of a new, psychologically informed expertise. Growing consumerism urged emotional investment in acquisition and goods, and this diverted from some of the emotional investments that figured powerfully in the eighteenth and nineteenth centuries. Corporate and service employment required higher levels of emotional self-manipulation, in order to turn on a friendly smile and avoid bureaucratic confrontations. 'Impersonal, yet friendly' became a literal watchword in business training programs, with considerable emotional implications. At the same time, popularizing experts now referred to their psychological, rather than moral credentials, creating a picture of a more fragile mental structure than had previously prevailed. A recent study (Pfister and Schnog, 1997) further probes the particular American fascination with psychological explanations and remedies, as a framework for contemporary emotional life.

The consequences of change involved, as with earlier redirections, both personal and social features. Americans became more nervous about emotional display, convinced that intensity reflected immaturity on their part; hence a recent study emphasizes a proclivity to check with others about onsets of jealousy, in order to provide a peer mirror to guard against lack of restraint. Other studies (Salovey, 1994) show the consequences of rigorous emotional control on the job, in distorting responses even in private relationships. Legal changes, including the rise of no-fault divorce, incorporated the growing belief that moderns should be able to keep anger and grief in check, in the most trying circumstances. Even changes in protest rates – the marked decline of labor strikes after 1958 – derived in part from successful efforts to persuade workers that anger was childish, a reflection of personal flaw rather than a valid emotional response to objective problems. The reach of this new change in basic emotional style, in sum, was considerable.

Finally, amid growing constraints on certain emotional expressions, a recreational culture arose that provided some symbolic contrasts. Intense spectatorship, for example at sporting events, played off against normal emotion management, and athletes and actors were allowed displays of anger, grief, or vivid camaraderie that were not usually countenanced – providing, in other words, what has been described as a compensatory surrogate culture.

Exploration of the two great transformations has involved the work of a substantial number of historians and historical sociologists. Inevitably, even in a new field, some disagreements have surfaced. Specific emphases and attributions of cause differ in the approaches to the early modern transformation. French work divides between explorations of distinctively Catholic features (as in the work on fear) and a sense that French emotional culture moved in harmony with other parts of Europe (as in the work on familial affections; see Delumeau, 1978). Divisions, though not outright clashes, also inform the work on the twentieth-century turning point. European sociologists have worked more on the process of 'informalization' than have their American counterparts, arguing that contemporary emotional relations work because people can assume successful incorporation of the rules of restraint (Wouters, 1992). American historians accept this conclusion, in part, but additionally point to important new regulations and tensions. No coherent schools have emerged as yet, but there are fruitful debates.

Both of the great changes in emotional standards raise a host of questions, headed by the problem of social class. The rise of new standards of love in the eighteenth century involved a variety of social groups; proletarians, free from the constraints of property arrangements, may have moved early to emphasize a type of love more fully (Gillis, 1985). But some of the standards particularly attached to the rising middle class. Emphasis on heightened emotional sensitivities between parents and children, for example, while no monopoly of a single class, moved into a bourgeois lexicon; and many observers criticized workers for failure to display the finer parental feelings. Changes in the twentieth century did have a democratic air, in that nineteenth-century attempts to downplay certain groups as impossibly crude noticeably declined. Romantic love was a case in point. American jurists in the late nineteenth century had been willing to allow lack of love as a valid reason for divorce for middle-class people, under the heading of mental cruelty, but they would not do the same for the working class because such emotional refinement was impossible at this level. In the twentieth century, however, the now-modified romantic love ideal was proclaimed for all. Still, issues of how particular emotional standards affected social classes are only now beginning to receive needed attention. One study, for example, shows how new hostility to the use of fear in childrearing, an American middle-class staple by 1900, captured Catholic working-class culture only in the 1950s. In other instances, middle-class prescriptions were not simply more slowly assimilated by other groups, but were positively defied, as in some of the more emotionally exuberant facets of twentieth-century African American culture (Stearns and Lewis, 1988).

Current Issues and Future Directions

The success of historical work to date considerably adds to available information on varieties of emotional formulations and the ways values and emotions interact. It thus amplifies the constructionist approach to research on emotion, arguing that a significant part of emotional codes and responses vary with context – by place, but also by time period. The exploration of change and causation builds a further ingredient into constructionism, often missing from anthropological studies, in showing how one emotions variant may transform into another, responding to wider factors in economic, political, and cultural structure.

The historical agenda also raises problems, even aside from the range of areas and periods, and types of emotions, still open to this kind of analytical inquiry. The relationship between widely prescribed cultural standards and other aspects of emotional experience – aspects that usually leave less explicit past records – is an obvious issue. Standards count in themselves: they affect social rules and practices, based on expected emotional behavior; they color evaluations of others and of self; and they unquestionably shape actual experience. Thus a culture that discourages romantic love – a common pattern in premodern peasant societies – almost certainly has less of it. But there are disjunctures as well, and historians must be sensitive to these. Among other things, emotional experience may vary somewhat less than standards do. Historians who initially assumed that the absence of explicit encouragement (indeed, the considerable explicit hostility) to marital love, in prescriptive materials before the seventeenth century, meant that there was in fact little, were assuming too much, and more recent researchers have improved on the evidence available in generating more nuanced statements of contrast and change.

A related issue, now happily beginning to gain constructive attention, involves subcultures. As noted previously, most emotions history to date has focused on mainstream standards issuing from dominant social groups. Various social classes, religious contingents, even age categories form emotional cultures of their own. Research in American history, particularly, is beginning to reveal patterns of emotionology in various religious and racial groups, and in the working class.

These patterns sometimes link to mainstream trends, if with a certain chronological lag, but they sometimes deliberately run counter – as in the enthusiastic religious sects that arose around 1900 as an antidote to growing mainstream hostility to emotional intensity.

Comparison also deserves more attention. The extensive focus on large transformations invites fine-tuning. Most research on both the early modern and the twentieth-century turning points has been either strictly national (just the USA or just France) or has assumed large transatlantic, Western trends. Yet we know that in the year 2000, in key particulars, regional patterns vary – the French get angry when jealous, the Dutch sad, while Americans scurry to get other people's opinions. We need explicit historical comparisons to determine when, and above all why, distinctions of this sort emerged.

History can also establish middle-level generalizations about emotional change, based on the accumulation of cases. We can begin to use partial models of the factors most likely to cause change, and about the length of time normally required between the introduction of widely shared new standards, and actual changes in social arrangements and behaviors (including childrearing). It took about a century, for example, for warnings against scaring children with bogeymen stories to gain sufficient acceptance that the prescriptive emphasis could be cut back (after the 1920s). Thirty years elapsed between new strictures against anger in the workplace, and incorporation of the same standards in parenting advice; and almost 40 years between the new culture's inception and clear implementation in laws and protest levels. These are straws in the wind, toward more systematic statements about timing.

In what is still a new field of explicit research, despite promising results to date, dealing with empirical and theoretical gaps inevitably forms a challenging agenda for the future. Identifying subcultures has barely begun, for example in dealing with racial differences over emotional goals in the USA. Geographical omissions are troubling in themselves, and they limit opportunities for comparison. Even for the Atlantic world, where the literature is richest, comparative opportunities have barely been taken up. With all this, two additional challenges remain: further integration with history, and further integration with the other disciplines that examine emotion.

The number of historians interested in emotion has expanded steadily. But findings about emotional change are not usually incorporated into mainstream historical study. Family historians come closest to recognizing the importance of this topic, as an element for example, along with birthrates and the roles of family members, in establishing periodization. But the day when historians of protest or politics consider the role of shifts in emotional standards has not yet arrived. The connection is possible: at a time when the emotional reactions of American politicians are carefully scripted in light of the dominant emotionology, there is obvious invitation to explore mutual interactions between culture and political reactions in the twentieth century (Kofler, 1997). The same holds for studies of sports or labor relations. While the record to date is tentative at best, there is reason to assume that fuller integration will occur, as historians become more comfortable with the idea that emotional standards shift and that shifts have important consequences.

The even greater challenge for the future is interdisciplinary. Historians of emotion have found ready audience among anthropologists, sociologists, and some social psychologists (particularly, of course, those theoretically wedded to a discursive, cultural-constructionist approach). But actual interdisciplinary projects, which would deal with change and impact in relation to current emotional manifestations, have yet to emerge. Mainstream psychology focuses primarily on invariant aspects of emotional display such as facial expressions, and ignores issues of cultural variance and change (Harré and Stearns, 1995). We lack the collaboration necessary to use historical analysis to help test the boundary lines between inherent emotional components and the role of cultural standards, yet precisely this collaboration constitutes a vital next step. Projects that would identify recent change and subject the emotional results to standard psychological scrutiny are possible – for example, the tentative signs, since the 1970s, of partial modification of the contemporary hostility to grief. But constructing the interdisciplinary apparatus that can handle such issues is no easy task, given the growing split between cultural analysis and scientistic psychology. The desirable agenda is obvious; its realization, distinctly problematic.

Even as things stand, the history of emotions is contributing not only to an understanding of emotion, but also to a wider assessment of emotion's impact on behaviors and social institutions. Too often, emotions research focuses on individual experience. Even in the short time explicit emotions topics have commanded their attention, historians have advanced the exploration of why particular emotional articulations matter – how they affect the experience of family life and friendship, how they connect to regimens at work, even – in some extensions currently being developed – how they can help shape new political styles. Historians will continue to probe emotional characteristics in the past and particularly cases of significant change; but they will also be eager to fold emotion actively into our larger understandings of how societies function. Momentum continues to build in this active new disciplinary partner in emotions research.

Abstract

Emotions are brief episodes during which several functional components are synchronized in response to an eliciting event. Emotions can be assessed by measuring responses in each of these components: subjective feeling, physiology, expression, and motivation. In this article we review the most advanced methods that can be used to assess emotions in each of the four components: self-report measures and questionnaires, measures of physiological activation, instruments for the analysis of nonverbal expressive behavior, and behavioral tasks.

Introduction

Even if the exact definition of 'emotion' is still a matter of debate between theorists, there is general consensus about the main components of an emotion episode (Frijda and Scherer, 2009). An emotion episode is originated by the appraisal of an eliciting event that causes synchronized changes in four main components: a physiological component, an expressive component, a motivational component, and the subjective feeling (Mortillaro et al., 2013). The changes in these four components are, therefore, informative of the state of the person and can be used as indicators of an emotional experience. Emotion assessment methods, indeed, can be grouped based on which of these four components they target.

In this article we review some of the measures that have been proposed to assess emotions and group them according to the component to which they refer. We focus on methods that are elaborated for nonclinical adult human samples. We will not consider all the instruments that were used for the purpose of better understanding the key elements of an emotional experience, namely cognitive antecedents (e.g., the GRID questionnaire; Fontaine et al., 2007), correlates of emotions, and emotional personality traits.

Two components have received particular attention in the context of emotion assessment: subjective feeling, by means of questionnaires and self-report measures; and expression, by means of coding instruments built to objectively measure facial, vocal, and bodily expressions. Physiology has been the object of several studies but researchers mostly focused on the existence of emotion-specific physiological patterns and clear indications about how using physiology to assess emotions are yet to come. The motivational component is the least studied and we will discuss it only briefly.

Subjective Feeling: Emotion Assessment through Questionnaires and Self-Report Measures

The subjective feeling is the holistic cognitive representation of all the changes elicited by the emotional event; this representation allows the individual to be aware of his/her state and name it with a particular emotion label (Scherer, 2009). Self-report measures are probably the best (if not the only) way to get the individuals' conscious representation of their emotional experience. Nevertheless, when using a self-report measure, the researcher should always consider the risk of social desirability of the responses and the variability that exists between individuals with respect to the ability or the willingness to report on emotional states.

There is not one standard self-report measure or procedure that can be used for any purposes in any context, but rather there are several self-report measures, each of which has specific contexts of application, and theoretical implications. As a general remark, state of the art self-report measures are based on clear theoretical grounds, are empirically validated, and are used to assess current emotional experience rather than reports about past or future events, and stable emotion-related traits (Mauss and Robinson, 2009).

Instruments to assess the emotional subjective feeling can be divided into four groups, defined along two major axes. The first axis is the theoretical model they refer to emotions as discrete categories (Ekman et al., 1983; Izard, 1977) or emotions as states defined by dimensions (Russell, 1980). The second axis is the visual format of the instrument: purely verbal (only text) or instruments that include pictorial elements. Generally speaking, purely verbal measures – in the format of adjective checklists – have the advantage of being more specific and precise when measuring the individuals' subjective feeling. The pictorial instruments, however, are generally faster to administer and easier to understand for the respondents, and, more importantly, they do not rely on verbal knowledge and, therefore, do not need translation to be used in different cultures and can be administered to populations that do not possess complex verbal knowledge (e.g., children).

The discrete emotion approach is used to categorize the experience into separate states that are labeled with emotion words. Most frequently, this has been done through text-based instruments that ask people to rate the extent to which they experienced certain emotional state in a specific context, period of time, or in response to a stimulus. The exact form in which the ratings are given differs across instruments. Several studies assess emotions by simply asking to choose one emotion label from a predefined list of emotion words (nominal level). Some adjustments have been suggested in order to improve the

reliability of this procedure; in particular, respondents should have the possibility of choosing an option 'no emotion' and to be allowed to indicate another emotion label that is not included in the list (Bänziger et al., 2012; Scherer, 2005). One-item nominal answers provide quick access to a global estimate of the subjective feeling of the person, but the reliability remains rather low. Using multiple items to assess an emotional state has greater reliability and can assess a larger part of the emotional spectrum. These procedures require the respondents to rate on a scale (ordinal or interval level) the extent to which each one of a list of emotions was experienced. In the following paragraph we describe some of the most commonly used text-based measures that adopt a discrete perspective.

The most frequently used instrument in this tradition is the *Differential Emotion Scale* (DES; Izard, 1977; Izard et al., 1993). The DES "is a standardized instrument that reliably divides the individual's description of emotion experience into validated, discrete categories of emotion" (Izard, 1977: p. 124). Subjects indicate on 5-point scales (from 'not at all' to 'very strongly') the strength of their feelings using an adjective checklist made of 30 items. These 30 items are grouped in 10 discrete emotion categories, or factors, and were derived from cross-cultural studies on emotion–expression labeling (Izard, 1971). The 10 factors are: anger, surprise, interest, contempt, fear, guilt, shame/shyness, joy, sadness, and disgust. Other versions of the instrument have been proposed over the years. In the DES II, the item content was refined and the instructions changed to allow the assessment of emotions experienced over extended time periods (Izard, 1972, 1977). The DES III is a version of the DES adapted for children and adolescents and includes phrases that describe the subjective feeling associated with each primary emotion (Kotsch et al., 1982). The DES IV (Izard et al., 1993) includes 12 factors instead of 10, with separate scales for Shame and Shyness, and a new scale for Self-Hostility.

Another 'text-only' instrument is the emotion part of the *Stress Questionnaire* by Foikman and Lazarus (1985). This questionnaire was developed in the context of stress research and includes a section about emotion. The subjects are asked to indicate on a 5-point Likert scale the extent to which they felt each of 15 emotions, grouped in 4 scales. The score for each scale is computed by summing the ratings for each item. The four scales are based on the main appraisal theme of the emotions: Threat emotions (worried, fearful, and anxious); Challenge emotions (confident, hopeful, and eager); Harm emotions (angry, sad, disappointed, guilty, and disgusted); and Benefit emotions (exhilarated, pleased, happy, and relieved).

Discrete emotions can also be assessed through instruments that include graphical elements that are designed to simplify the task for the respondents. The Geneva Emotion Wheel (GEW; Scherer, 2005; Scherer et al., 2013a) consists of several discrete emotion labels arranged in a circle. The disposition of the labels is determined by the position of the emotions in a two-dimensional space defined by valence and control/power according to both theoretical modeling and empirical data (Scherer et al., 2013a). The intensity of the emotion is mapped on the distance between the center and the rim of the wheel. Respondents can choose the emotion and indicate its intensity by choosing one of the circles that connect the emotion label to the center of the wheel: the size of each circle corresponds to the intensity of the respective emotion. The specific choice of emotions included in the GEW is not fixed. Users can modify the choice of terms for their specific research purposes but they should respect the underlying theoretical structure.

An example of a purely pictorial instrument to assess discrete emotions is The Product Emotion Measuring Instrument, an instrument that was specially developed for measuring emotional responses to products (PrEmo; Desmet et al., 2007). PrEmo is a self-report instrument that uses cartoon characters to represent emotions. The character expresses seven positive emotions (inspiration, desire, satisfaction, pleasant surprise, fascination, amusement, and admiration), and seven negative emotions (disgust, indignation, contempt, disappointment, dissatisfaction, boredom, and unpleasant surprise.) The interface includes still pictures of the character's animations with a three-point scale: "I feel the emotions," "to some extent I feel the emotion," and "I do not feel the emotion."

The measures built on the basis of a dimensional account describe the emotion experience on a number of underlying dimensions. The specificity of the instruments that adopt a dimensional approach is in the output that they provide more than in their format – adjective checklist. These instruments vary in terms of the emotional dimensions that they are targeting.

The Positive and Negative Affect Schedule (PANAS; Watson et al., 1988) is the most frequently used adjective checklist in the dimensional tradition. The PANAS is an adjective checklist made of 20 emotion items that are used to estimate the emotional experience of the respondents in terms of two orthogonal dimensions: Positive Affect and Negative Affect. Positive Affect represents the extent to which a person is enthusiastic, active, and alert; Negative Affect represents general distress and unpleasant engagement. Respondents are asked to use a 5-point unipolar intensity scale for each of the 20 items to describe their emotional experience. The PANAS has published normative and clinical data; it provides an interval scale level, and has been used in several research domains. A more recent version is the PANAS-X, which includes 60 items that measure the same two higher order scales of the original PANAS (Positive Affect and Negative Affect) in addition to 11 specific affects (Fear, Sadness, Guilt, Hostility, Shyness, Fatigue, Surprise, Joviality, Self-Assurance, Attentiveness, and Serenity; Watson and Clark, unpublished manuscript).

An alternative dimensional model is the Pleasure-Arousal-Dominance model (PAD), which assumes that these three independent dimensions are necessary and sufficient to describe emotional states (Mehrabian and Russell, 1974; Russell and Mehrabian, 1977). Unlike the PANAS, the PAD model considers valence as one dimension. Mehrabian and Russell (1974) devised semantic differential scales to directly assess these three dimensions. Each of these three scales is made of six bipolar adjective pairs that are rated using a 9-point scale. More recently, Russell et al. (1989) suggested a single-item scale to measure two of the three dimensions of the PAD model, pleasure and arousal. This instrument, called Affect Grid, is a 9 by 9 grid in which the horizontal dimension represents pleasure and the vertical dimension

arousal: the respondents check one of the 81 cells to report their level of arousal and pleasure.

The Brief Mood Introspection Scale is an instrument that integrates both dimensional perspectives in the same adjective checklist (BMIS, Mayer and Gaschke, 1988). Indeed, the BMIS can be used to measure the mood in four continuous scales: Pleasant-Unpleasant scale; Arousal-Calm scale; Positive-Tired scale; and Negative-Relaxed scale. The checklist consists of 16 adjectives, 2 from each mood states: happy, loving, calm, energetic, fearful/anxious, angry, tired, and sad. The respondents rate each adjective using a 4-point scale.

Researchers in the dimensional approach frequently use the Self-Assessment Maniking (SAM; Bradley and Lang, 1994), a nonverbal pictorial assessment technique that directly measures pleasure, arousal, and dominance. The SAM is both a computerized and paper-and-pencil instrument that consists of three sets of graphic illustrations for each of the three major dimensions. The pleasant dimension is represented by 5 illustrations, with at one extreme a smiling figure and at the other end a frowning and inverted-U mouth shaped figure; the arousal dimension ranges from a wide-open-eyed 'excited' figure to a sleepy one (i.e., eyes are closed); the Dominance dimension is metaphorically represented in terms of the size of the figure (the bigger the size, the higher the feeling of dominance, control).

In the paper-and-pencil version of the SAM, the respondents can, for each dimension, mark one of the pictures or the space between any two of them to report about their feeling – resulting in a 9-point scale. This instrument is relatively easy to understand and faster to use compared to any adjective checklist. However, the output of this scale is based on a single item response per dimension.

Physiology: Autonomic Measures of Emotion

All emotion theories postulate that physiological changes are an inherent aspect of the emotional experience (Frijda and Scherer, 2009). Physiological changes happen in different organismic subsystems, but it is the autonomic nervous system (ANS) that attracted most of the researchers' attention. The ANS is the set of peripheral nerves and ganglia that modulate peripheral functions and it is made of two branches, the sympathetic system – generally associated with activation, – and the parasympathetic system – generally associated with relaxation. The activity of the ANS is implicated in several bodily functions that are not related to the emotion process per se; however, the emotional state of the individual can alter some physiological indices.

Most physiological measures used as indicators of emotion can be grouped in three functional groups: respiratory functioning (e.g., respiration rate), cardiac functioning (e.g., heart rate), and electro-dermal activity (e.g., galvanic skin response). Several studies followed the pioneering work of Ekman et al. (1983; Levenson et al., 1990) and aimed at identifying emotion-specific autonomic patterns. Recent reviews, however, do not explicitly confirm the existence of emotion specificity (Kreibig, 2010; Larsen et al., 2008). Although stable differences can be found between pairs of emotions (e.g., anger is associated to higher diastolic blood pressure than fear), the search for emotion-specific autonomic patterning is still inconclusive. Kreibig (2010) proposed that findings should be interpreted in the light of the motivational dispositions underlying the emotions. For example, decreased cardiac activity was associated with emotions characterized by an approach motivation, while an increase is found in emotions that are related to an active coping response to negative situations. Similarly, increased electro-dermal response happens in almost all emotions and may be a symptom of the motor preparation that is an integral part of the emotion episode (action tendency, Frijda, 1986), while decrease is found for all emotions in which passivity is the shared motivational state.

Researchers who did not focus on the specific associations between discrete emotion and physiological signals investigated, instead, physiological correlates of emotional dimensions like arousal and valence. Several studies found that physiological indices can be reliably used under controlled conditions to estimate the level of arousal/activation associated with an emotional experience. In particular, electro-dermal response was repeatedly suggested as a proxy to estimate the arousal level of the person experiencing an emotion: for example, in one very influential study, Bradley, Lang, and colleagues (2000) showed that the level of skin conductance is linearly correlated to the perceived arousing properties of emotional stimuli. In connection to the valence dimension, research findings seem to be less consistent. Several studies used facial Electromyography (EMG) to assess valence: In these cases, researchers placed electrodes on muscles that are supposedly involved in valenced responses, namely *zygomaticus mayor*, the muscle that pulls the lip corners upward producing a smile (usually associated with positive responses), and the *corrugator*, the muscle that lowers the eyebrow while pulling them together, producing the frown (usually associated with negative responses).

Expression: Emotion Assessment from Nonverbal Behavior

The study of nonverbal behavior has a particular status in emotion research, as it is at the core of some of the most influential emotion theories. For example, basic emotion theory (e.g., Ekman, 1992) was largely inspired by Darwin's (1872) seminal work on the evolutionary bases of emotional expression. Dimensional models of affect derived from studies on the perception of facial behavior (Schlosberg, 1952; Russell and Bullock, 1985), and componential theories of emotion view nonverbal emotional expression as a major component of affect (Scherer and Ellgring, 2007a; Smith and Scott, 1997). The dynamic systems approach of socio-emotional development is based on the study of nonverbal exchanges between infants and caretakers (Fogel et al., 1992). The study of nonverbal behavior also fueled major controversies about the role of emotion in communication and about the universality of emotional expressions (Fridlund, 1994; Owren and Bachorowski, 2003; Russell, 1994; Scherer, 1992).

To understand the connection between emotion and nonverbal behavior, it is useful to consider the former as a process of interrelated changes in several components of

psychobiological functioning (Frijda, 2007; Roseman and Smith, 2001; Scherer, 2001; Smith, 1989). In this view, emotional communication belongs to the motor expression component and would function to convey reactions and behavioral intentions to conspecifics (Scherer, 2005). Emotional expressions could also function to modify the internal states of perceivers in a way that is advantageous to signalers (Owren and Bachorowski, 2003), or to ensure the honesty of social signals as indicators of adaptive dispositions (Brown et al., 2003; Mehu and Scherer, 2012). It is believed that, from an evolutionary point of view, the function of emotional expression is better served by multimodal patterns of behavioral cues including facial, vocal, and bodily signals (Mortillaro et al., 2013; Scherer and Ellgring, 2007b). The measurement of these signals may therefore provide an objective, though indirect, basis to assess emotional experience (Ekman et al., 1980).

Face

Facial behavior has dominated the research on emotional communication, and different models have been proposed to account for the association between the face and affect.

The continuous development of coding schemes for the systematic measurement of facial movements testifies of the great interest in this research area. The most recent coding scheme to date, the Facial Action Coding System (or FACS, Ekman and Friesen, 1978), is a comprehensive, anatomically based system to measure facial behavior, which allows researchers to compare their results across individuals and cultures. Each functional muscular movement that happens on the face can be labeled with a specific code (Action Unit, AU). Combinations of action units can be used to describe, unequivocally, any possible facial expression. In addition, explicit rules for the coding of action units boundaries and phases (onset, apex, and offset) are included in the coding system. Because the use of FACS does not require interpretation about the mechanisms responsible for the activation of facial muscles, all researchers can use it, independently of their attachment to particular theoretical frameworks.

The most influential theory in facial expression research postulates that a limited number of discrete emotions – or families of emotion – have specific signatures in configurations of facial movements (Basic Emotion Theory; Ekman, 1992; Izard, 1971; Tomkins and Carter, 1964). In this view, specific configurations of facial actions indicate the presence of discrete basic emotions such as joy, anger, fear, or disgust, to name a few. The reliability of emotional signaling would be ensured by the presence, within these facial configurations, of movements that are not easy to manipulate voluntarily (Ekman, 2003; Mehu et al., 2012). Researchers who adopted this approach developed the Emotion FACS (EMFACS) in which coding is directly related to the facial movements and configurations that are considered signals of discrete emotions. Despite the popularity of the evidence in support of Basic Emotion Theory, a recent review suggests that the coherence between discrete emotions and facial behavior is relatively weak (Reisenzein et al., 2013).

Dimensional models of affect (e.g., Russell, 1980) postulate that facial movements are indicative of fundamental affective dimensions such as valence and arousal. In this view, specific facial movements do not represent discrete emotion categories but underlying dimensions of affect. For example, the pulling of lip corners (most commonly known as smiling) indicates positive valence, whereas eyebrow raise and eye opening would reflect emotional arousal (Snodgrass, 1992). Recent research has extended the number of underlying dimensions to four: valence, arousal, power/control, and predictability/novelty (Fontaine et al., 2007), and the association between these dimensions and facial behavior remains to be systematically tested. The links between emotional dimensions and facial action units are, however, unlikely to be specific, as a single facial movement may be associated with several dimensions (Mehu and Scherer, under review).

A third group of theoretical models, called Componential Models, suggests that the different elements of facial behavior (action units) reflect the outcome of cognitive appraisal processes, such as the evaluation of novelty, pleasantness, or coping potential (Scherer and Ellgring, 2007b; Smith and Scott, 1997). Appraisal models of facial expressions received empirical support in several studies. For example, the eyebrow frown is related to perceived goal-obstacles (Smith, 1989), and movements related to eye opening (such as eyebrow raise, and upper eyelid raise) are associated with the appraisal of novelty or unpredictability, namely, greater eye opening indicates perceived novelty (Mortillaro et al., 2011). The later study also revealed that cheek raise is associated with the appraisals of intrinsic pleasantness and goal conduciveness. Evidence in support of this model also comes from psychophysiological research in which a variety of AUs have been related to the outcome of appraisal processes (for a brief review of this literature, see Scherer et al., 2013b).

Voice

Voice has always been considered an important channel of emotional communication (Scherer, 1986). Research shows that infants as young as 5 months of age can discriminate happy from sad voices (Caron et al., 1988). People are able to reliably infer valence of nonlinguistic vocalizations (Fecteau et al., 2005), acoustic properties of speech can be used as an index of emotional intensity (Bachorowski and Owren, 1995), and mood change can be traced using vocal cues (Ellgring and Scherer, 1996). The voice is a powerful medium to communicate emotion, as it has a larger reach than signals that require the visual attention of perceivers in order to operate.

Although the relationship between voice and discrete emotion categories has not been researched extensively, a recent study suggests that basic emotions might have distinct vocal signatures (Sauter and Scott, 2007). People have been shown to accurately discriminate among different emotion categories on the basis of vocal cues only (Bänziger et al., 2012; Hawk et al., 2009), and there is some evidence that vocal emotional expressions are universal (Bryant and Barrett, 2008). The acoustic information used by perceivers to classify emotions is extremely varied and includes different measures of pitch (the proximal percept of fundamental frequency), vocal intensity, spectral measures, speech rate, and the duration of voiced periods (Banse and Scherer, 1996; Scherer, 1986). It is likely that the computation of new vocal parameters will,

ultimately, enlarge the list of vocal features related to emotional experience.

Like for faces, vocal expressions also convey information related to underlying dimensions of emotional experience. Arousal or activation is the main dimension that has been linked to voice (Banse and Scherer, 1996; Goudbeek and Scherer, 2010) and acoustic of speech can be used as an index of emotional intensity (Bachorowski and Owren, 1995). The vocal channel is also believed to convey information relative to the 'power dimension,' that is, the ability to control environmental situations (Goudbeek and Scherer, 2010). Emotion expressed in the voice varies according to the circumstances in which the emotion is produced as well as dispositional differences in positive and negative emotionality (Bachorowski and Owren, 1995), suggesting that cognitive appraisal of situations as well as emotional valence are connected to the vocal channel. Finally, it appears that the acoustic parameters involved in the production and perception of emotion share a common basis with sounds used in musical performance to express and elicit emotions (Juslin and Laukka, 2003).

Body

Body movements are of prime importance in the judgments of emotional experience (Montepare et al., 1999; Wallbott, 1998), psycho-affective disorders (Ekman and Friesen, 1974; Wallbott, 1985), and emotional arousal (Mehu and van der Maaten, 2014). Two aspects are important in the evaluation of bodily cues: Static configurations (or body postures) and movement quality. Body postures can be relatively stable over time and change much more slowly than facial and vocal cues. As a result, they have been considered as indicators of 'gross affective states' such as the feeling of pleasantness (Ekman and Friesen, 1969). On the other hand, the complexity of movement offered by the different body parts (e.g., hand and head movements) makes the body an important hub for the communication of subtle and transient emotional states. These ideas suggest that different properties of bodily cues could reflect different emotional information.

Despite the idea that the body is a rich source of emotional information (Darwin, 1872; Ekman, 1965), research on bodily cues of affect has been much less frequent than research on facial and vocal cues. The difficulty inherent to the development of systematic coding systems for bodily cues is probably the main reason for the paucity of research on body-affect relationships (Harrigan, 2005). In recent years, however, we have assisted new attempts at developing comprehensive coding schemes for body movements and postures, notably the Body Action and Posture coding system (BAP; Dael et al., 2012a). The BAP, inspired by the FACS, adopts an integrative approach to the dynamic description of body movement on an anatomical level (different articulations of body parts), a form level (direction and orientation of movement), and a functional level (communicative and self-regulatory functions).

In the same manner as in facial and vocal expression research, scholars interested in bodily cues of emotion have tried to isolate movements that are specific to discrete emotional states (Coulson, 2004; Tracy and Robins, 2008; Wallbott, 1998). However, specificity in movement patterns to emotional categories has not received conclusive support, as the same combination of movements often occurs in different emotional states (Dael et al., 2012b). For example, raising the arms up is found in expressions of both pride (Tracy and Robins, 2008) and joy (Boone and Cunningham, 1998; Wallbott, 1998). Instead, recent evidence suggests that patterns of body movements are associated with functional components of emotions (e.g., modes of appraisal and action readiness) that show considerable overlap between emotion categories (Dael et al., 2012b). Details about the bodily cues associated with emotion categories can be found in several studies (Dael et al., 2012b; Montepare et al., 1999; Wallbott, 1998).

Motivational Component: Assessing Emotions through Motor Actions

Despite the importance that all theories attribute to the motivational and action component of emotions (Frijda, 1986), there are very few studies that suggested to use motor actions (that are not considered as communicative units) to assess emotions.

Russell and Mehrabian (1978) suggested that the behavior of a person changes as a function of the emotion-eliciting quality of the environment, but did not consider the issue of emotion assessment. Motivational behaviors such as approach and avoidance are frequently used to estimate whether a stimulus is positive or negative and indirectly the valence of the reaction of the person (Chen and Bargh, 1999). However, several authors suggested that anger, a negative emotion, is also characterized by an approach motivation (e.g., Carver and Harmon-Jones, 2009; Wilkowski and Meier, 2010) and, therefore, motivational direction and affective valence should be dissociated (Coombes et al., 2007).

The most frequently used paradigm to estimate approach and avoidance reactions uses the movements of the arm of the respondent. Approach is associated with moving objects closer to a person, while avoidance is associated with pushing them away. For example, Marsh et al. (2005) found that angry facial expressions facilitated avoidance behavior that is, pushing a joystick away from oneself more quickly than pulling it closer.

In another version of the paradigm, the effect of pulling the joystick closer to the self or pushing it away from the self has the consequence to, respectively, magnify (i.e., increase the size) or shrink (i.e., reduce the size) the picture that is observed (Rinck and Becker, 2007). The perceptual effect is that the pictures are coming closer or moving away depending on the movement of the joystick. Nevertheless, recent work questioned the absolute validity of such tasks by showing that a modification in the instructions would cause different results than predicted (Eder and Rothermund, 2008). This led these authors to argue that evaluative implications of the instructions assign affective codes to motor behavior that interact with stimulus evaluation.

Conclusion

Past research showed that several instruments can be used to assess the emotional state of a person. Nevertheless, our review

showed there is not one single method for emotion assessment that is ideal under all circumstances. The choice of the method depends on the research question and on the resources available for the realization of specific research designs. Most importantly, researchers should look for the method that best allows them to test their hypotheses, and consider using multiple assessment measures at the same time in order to increase the internal validity of their studies.

Abstract

Emotions are short-term episodes involving feelings, cognitive appraisals, motivational action tendencies, motor expressions, and physiological changes. External or internal events elicit emotions. Emotions have been shaped by evolutionary adaptation and by sociocultural contexts. Theorists disagree about the relative importance of and the interrelations between emotion components, the differentiation of emotional from nonemotional episodes, the relative extent of evolutionary and sociocultural impact (more universality vs more cultural specificity), and the dimensionality of the emotion space. Future directions in emotion research focus on aesthetic and positive emotions, emotions in social contexts, brain correlates of emotions, and interdisciplinary approaches to studying emotions.

Psychological research has identified particular characteristics of emotions that distinguish the scientific use of the term 'emotion' from its use in lay terminology, and that are used to differentiate emotions from other affective phenomena, such as moods (Section Characterizing Emotions). Beyond this relatively consensual view, however, different schools of thought in emotion psychology propose alternative answers to central questions about emotions (Section Alternative Answers to Four Central Questions Proposed by Four Families of Emotion Theories). Research programs resulting from the different theoretical perspectives have brought forth specific, and to some extent complementary, bodies of knowledge (Section Complementarities of Different Perspectives). Current developments in emotion research include the continued attempts to resolve ongoing controversies about the nature of emotions, research on the previously understudied aesthetic and positive emotions, emotions in social contexts, brain correlates of emotions, and the interdisciplinary study of emotions (Section Future Directions; see also Shuman and Scherer, 2014).

Characterizing Emotions

Emotions Are Triggered by Events

Emotions are generally elicited by actually occurring, remembered, or imagined events (e.g., failing at a task, remembering past failures, or worrying about potential failures). In some cases emotions may also be caused by direct neurophysiological factors (hormones, drugs) or entrainment (e.g., music; see Ellsworth and Scherer, 2003). A defining characteristic of emotions is that they are about something: emotions have an "event focus" (Mulligan and Scherer, 2012: p. 346). However, individuals are not always consciously aware of the stimuli or situations that have aroused the emotion.

Emotions Are Short Term

Emotions have a short duration. Typical anger and joy episodes, for example, last between 15 and 60 min and fear episodes up to 15 min (Verduyn et al., 2009). The short duration can be attributed to the prevalence of rapidly changing situations: changes occur in the object of the emotion, the individual experiencing the emotion, and the relation between the object and the individual (e.g., fear aroused by a growling dog may change when the dog stops growling, when one finds a big stick, and when one increases the distance from the dog, respectively). Situations are also altered after habituation (e.g., one gets used to the dog's growling). Personality and situational variables influence how long everyday emotional episodes last.

Emotions Are Multicomponential

Emotions involve multiple components that are associated with different functions. A subjective feeling component, a motor expression component, and a physiological component have long been considered central to emotions. Later, an additional action tendency component was advocated. Furthermore, during the cognitive revolution in the social and behavioral sciences, a cognitive appraisal component was added. However, some argue that the appraisal component is not a part of emotions but that it is rather an antecedent of emotions (see Moors, 2009).

The subjective feeling component is often used synonymously with 'emotion' or 'affect.' However, many emotion researchers regard affect as a superordinate category that includes emotions but also moods and other affective phenomena, and they define subjective feelings as one of several emotion components. The subjective feeling component is evident in verbal expressions such as 'feeling good,' 'feeling happiness,' 'feeling anger,' or 'feeling gratitude.' The function of this component is to monitor the individual's state. For example, feeling anger allows the individual to take regulatory efforts to reduce anger and feeling less anger gives the individual feedback that the regulation was successful. The monitoring function is important for regulating emotions when an individual is alone (at the intraindividual level) and when interacting with others (at the interindividual level; see Keltner and Haidt, 1999).

The function of the cognitive appraisal component is to determine the meaning of a situation for the individual regarding the situation's causes, consequences, and required

behavioral reactions. In particular, appraising an event as relevant to the self is considered a defining feature of emotions. Additional appraisals (e.g., who is responsible for the situation or whether the individual can adapt to or change the situation) enable the individual to better understand the causes of a situation and its consequences, and to assess the most promising alternatives for behavioral adaptation. Appraisals can be processed unconsciously or consciously by an expressive motor, schematic, and conceptual system (e.g., Leventhal and Scherer, 1987). Knowledge about appraisals enables the individual to regulate the occurrence of emotions in the self and others by predicting when emotions will arise. At the interindividual level, appraisals also facilitate the communication of emotional knowledge.

The action tendency component refers to the prioritization and preparation of behavior based on the appraised meaning of the situation. This motivational component allows for flexibility as to which behavior will be carried out, if any. For example, feeling afraid is associated with an urge to avoid the situation, but an organism can decide whether or not to follow that urge and how to do so. 'Control precedence' is a defining feature of emotions (Frijda, 2007) and is particularly important at the intraindividual level.

Observable facial, postural, and vocal expressions are part of the motor expression component. This component serves a communicative function at the interindividual level (e.g., a smile can communicate happiness). Additionally, the motor expression component supports action tendencies. For example, Susskind et al. (2008) showed that disgust expressions lead to sensory closure, which may support the action tendency to dispel the source of the disgust. The motor expression component is therefore also relevant at the intraindividual level.

Changes in the subjective feeling, appraisal, action tendency, and motor expression component have neurophysiological underpinnings. For example, feelings are generated by an integration of different neural structures and circuits, including somatovisceral proprioception (Kreibig et al., 2010). Appraising an event as relevant to the self is associated with increased activity in the amygdala and different areas in the frontal cortex (Sander et al., 2005). Other appraisals, such as moral judgments, are processed in the neocortex. Furthermore, action tendencies generate changes in the endocrine and autonomic nervous systems. Motor expression commands generated in the brain are executed by the somatic motor system. The ubiquity of underlying neurophysiological processes in the subjective feeling, appraisal, action tendency, and motor expression component notwithstanding, researchers have postulated a separate 'physiological' or 'somatic' component – mostly referring to autonomic and visceral phenomena – to highlight the importance of the respective symptoms independently of overt emotional behavior and facial, postural, and vocal expressions.

Emotions Are Particular Kinds of Affective Phenomena

The characteristics of emotions (i.e., evoked by events, of short duration, and having specific components) distinguish them from related affective phenomena. In particular, moods, attitudes, preferences, and affect dispositions differ from emotions (Scherer, 2005).

First, the event focus of emotions distinguishes them from moods, attitudes, and preferences. Unlike emotions, moods generally do not have an object. Moods have causes, such as hormones, but they are rarely focused on any specific cause. The event focus also differs for attitudes. Although attitudes involve beliefs about an attitude object, the attitude object need not be present in reality or in imagination to trigger the attitude. Similarly, preferences are relatively stable and do not depend on triggering events.

Second, the short duration of emotions distinguishes them from longer lasting moods. Similarly, attitudes, preferences, and affect dispositions typically last longer than emotions.

Third, emotions have more specific action tendency components than attitudes and preferences that tend to be associated with general approach–avoidance motivations. Across situations, attitudes, and preferences may be good predictors of behavior, but within a particular situation, ongoing emotions may be stronger and more specific determinants of behavior.

Finally, the subjective feeling component of emotions is more differentiated than the affective component of attitudes and of preferences. Valence (positive–negative) similarly characterizes emotions, attitudes, and preferences. However, the subjective feeling component of emotions is additionally described by a power, arousal, and novelty dimension (see Fontaine et al., 2013). The feeling component also distinguishes emotions from affect dispositions (also called trait emotions). A disposition is not an affective experience itself, but an enduring tendency to more readily experience a specific mood or emotion (e.g., an angry or an anxious personality trait, Spielberger and Reheiser, 2009).

Emotions Are Shaped by Evolution and by Sociocultural Contexts

Fundamental debates in psychology center on the question to what extent a phenomenon is the result of evolutionary or social influences. An implication of an evolutionary view on emotions is that emotion triggers, experiences, and consequences are similar across cultures (and, to some extent, across species). In contrast, an implication of a social constructionist view is that emotion triggers, experiences, and consequences vary across cultures. There is increasing evidence that both of these factors determine emotion jointly and that their relative importance may vary depending on the nature of the emotion and the respective situation.

Emotions evolved because they have been adaptive in several ways. First, the action tendency associated with particular emotions can foster survival (e.g., fear from a threat is associated with an impetus to run away and avoid the threat). At the same time, the link between emotions and actions is sufficiently flexible to allow the organism not to carry out an action tendency (e.g., standing one's ground in a threatening situation, if need be). In contrast to reflexes, the behavioral repertoire of organisms with emotions is therefore more flexible. Second, the motor expression component associated with emotions is a means to communicate to others that a situation is desirable, threatening, and so forth, and can thereby increase

the fitness of one's in-group. Third, the feeling component allows the individuals to regulate their emotions, improve the match of situational requirements and actions, and ensure group harmony; as a result, personal and group fitness is enhanced. Fourth, the appraisal component allows the organism to make meaning of a situation, to learn for the future, and to communicate to in-group members, thereby increasing personal and in-group fitness.

In addition to evolutionary influences, emotions are shaped by sociocultural factors (attitudes, values, or norms in families, peer groups, nations, generations, etc.) in several ways (e.g., De Leersnyder et al., 2013). First, social groups partially determine which stimuli an organism is exposed to (e.g., certain foods are more common and arouse more positive emotions in one culture than another). Second, social groups influence how events are appraised (e.g., whether agency is typically attributed to the self or not). Third, social groups influence which and how much of an emotion is seen as a normal/deviant and as a desirable/undesirable experience for particular people in particular situations (e.g., big boys do not cry); in other words, culture influences how emotions are normatively evaluated. Finally, social groups influence how emotions should be communicated to others, including display rules and emotion terminology (e.g., men should express their love by proposing marriage and women by saying 'yes').

Alternative Answers to Four Central Questions Proposed by Four Families of Emotion Theories

Beyond the convergent views on the characteristics of emotions described in Section Characterizing Emotions, emotion theories propose different answers to central questions about the psychological structure of emotions. Regarding the question of how emotion components relate to each other, the received opinion among philosophers and scholars in the Darwinian tradition has been that the components are lawfully organized, driven by the evaluation of the triggering situation. In contrast, some early emotion researchers suggested that emotions are the perception of emotion-specific bodily activity, or that emotions result when unspecific arousal is attributed to a situational context (James, 1884; Schachter and Singer, 1962). To date, basic emotion theorists, appraisal theorists, social constructionist theorists, and nonlinear dynamic systems theorists still propose alternative answers to this question (**Figure 1**). Theorists from these four schools of thought also respond differently to the question of how emotional episodes differ from nonemotional episodes, of how strongly an emotion is influenced by evolution and social contexts, and of how to structure the emotion space (for further details, see, e.g., Moors, 2009).

What Are the Respective Roles of and the Interrelations between Emotion Components?

In basic/discrete emotion theories (e.g., Ekman, 1992; Izard, 2007; Panksepp, 1998; Plutchik, 2001), no one emotion component is more central than another. The components are seen as jointly triggered. Component patterns occur in particular types of situations. For example, the component pattern of a fearful facial expression and an urge to run away is triggered in a threat situation, whereas the component pattern of an angry facial expression and an urge to attack is triggered in a hostile interaction.

In contrast, appraisal theories (e.g., Ellsworth and Scherer, 2003; Lazarus, 1968; Ortony et al., 1990; Roseman et al., 1996; Scherer, 2009) propose that appraisals precede and cause changes in the other four emotion components. Appraisals may be processed simultaneously and yet have an interpretable output only in a specific sequence. For example, logically goal obstructiveness appraisal outputs should precede coping potential outputs and not vice versa, as coping depends on the nature of the obstruction (Scherer, 2009). Subjective feelings are seen as an integrative representation of changes across emotion components.

In constructionist theories of emotions (Barrett, 2006; Russell, 2003), a combination of the subjective feeling component with none, few, or all of the other emotion components forms an emotion. The subjective feeling component is specified as core affect consisting of valence (positive–negative) and arousal (calm-excited). An emotion results when core affect is combined with emotional knowledge about emotion terms and scripts that describe or prescribe the appropriate pattern of emotion components for particular situations. Subjective feeling with no other emotion component can be experienced as an emotion when, for example, a particular emotion term is extremely salient (e.g., due to laboratory manipulations). As the salient conceptual knowledge generally varies across situations, individuals, and groups, so do the emotion components that are integrated with the subjective feeling to form an emotion.

Nonlinear dynamic systems theories (Camras, 2011; Fogel et al., 1992; Lewis, 2005) propose a nonlinear relation between the emotion components. Emotions result when attractor states are reached through the self-organization among the emotion components by nested positive and negative feedback loops. Any emotion component may draw the other emotion components into an attractor state. For example, smiling may cause feelings, appraisals, and physiological changes to take on the attractor state of happiness.

To summarize, basic emotion theories propose that all emotion components occur jointly, appraisal theories view appraisals as causing changes in the other four emotion components, psychological constructionist theories suggest that emotions are constructed from subjective feeling (core affect) in combination with none or all of the other components, and nonlinear dynamic systems theories argue that any emotion component can cause changes in the other components.

How Are Emotional Episodes Distinguished from Nonemotional Episodes?

A second controversy among emotion theories concerns the question of how emotions can be differentiated from nonemotional states. In basic emotion theories, an emotion sequence consists of a baseline, a stimulus, a discrete emotion, and a return to the baseline. Emotions that occur in response to an external (real or imagined) stimulus are differentiated from homeostatic drives (e.g., hunger, thirst) that occur in response to internal signals from the body and motivate the organism to maintain the body's internal milieu. Therefore, the baseline of

Figure 1 Theoretical perspectives on the relation among emotion components and the differentiation of emotional from nonemotional episodes. First published in Shuman, V., Scherer, K.R., 2014. Concepts and structures of emotions. In: Pekrun, R., Linnenbrink-Garcia, L. (Eds.), International Handbook of Emotions in Education. Routledge, London, pp. 13–35.

homeostatic drives is called homeostasis, but the baseline of emotions is not.

Appraisal theories propose that individuals constantly appraise their environment. As a result, states that are not considered full-blown emotions are characterized by variable activities in all emotion components, including appraisals. An emotion occurs when an event is appraised as highly relevant to the individual's goals and needs; other appraisals then differentiate among emotions. An additional criterion to distinguish emotions from nonemotions is that changes in appraisals and other components are synchronized in time (Scherer, 2009).

In psychological constructionist theories, core affect can lead to an emotion when emotional knowledge is either attributed to perceived core affect (Russell, 2003) or integrated with it (i.e., in a conceptual act; Barrett, 2006). The boundaries of an emotion are entirely dependent on the conceptual knowledge about emotions.

With nonlinear dynamic systems theories, an emotion is seen as a particular kind of state in a succession of attractor states. Emotional attractor states are seen as special because they are "motivationally charged" (Fogel et al., 1992: p. 133). As attractor states are locally stable energy minima, a large change in one or more of the emotion components may be needed before a change from one to another attractor state occurs (i.e., phase shift). For example, a spouse may stay calm when faced with an increasingly frustrating situation, but once the spouse is angry, it may take a large change in the situation to reduce the anger. As a result, the relation between a stimulus and an emotion is not linear (the degree of frustration from the event does not correspond one-to-one with the anger), but depends on the previous state of the system (i.e., calm or angry). In other words, knowledge about preceding states is needed to predict future states.

To summarize, basic emotion theories suggest that emotions differ from nonemotional states because of the joint activity in

all emotion components, appraisal theories propose that the appraisal of an event as highly relevant and component synchronization characterize emotions, psychological constructionist theories suggest that emotions are differentiated by conceptual knowledge about emotions, and nonlinear dynamic systems theories associate emotions with motivational charge.

To What Extent Are Emotions Influenced by Evolution and Sociocultural Contexts?

Emotions are subjected to the influences of evolution and social contexts, but theorists disagree about the relative importance of these influences. Building on Darwin's work (1872/1998), basic emotion theorists suggest that for a limited number of basic emotions (sometimes described as 'affect programs'), the entire package of emotion components has evolved jointly to meet the fundamental needs of survival that occur throughout evolution. Therefore, basic emotions are thought to be universally shared by humans and, to varying degrees, by other species such as the great apes. Some basic emotion researchers suggest that throughout ontogenetic development, basic emotions become influenced by cultural pressures through stimulus selection and display rules (e.g., Ekman, 1992); others suggest that when basic emotions are influenced by culture, they give rise to complex emotion schemas (e.g., Izard, 2007). Social influences on appraisal tendencies of events are less emphasized but also considered by basic emotion theorists (e.g., Ekman, 1992).

Unlike basic emotion theories, appraisal theories suggest that evolutionary pressures shape in particular the links between appraisals and other emotion components. Across cultures, the same appraisals lead to the same emotions. Social contexts influence the triggering stimuli, the appraisal tendencies in a situation, and the evaluation and communication of emotions.

In psychological constructionist theories, only core affect has evolved. Constructionist theories propose that there are no natural relations between situation types and emotions (as in basic emotion theories), or between appraisals and other emotion components (as in appraisal theories). Social pressures determine conceptual knowledge about emotions, which define the boundaries of an emotion. Systematic relations among emotion components can be attributed to shared conceptual knowledge among individuals.

Nonlinear dynamic systems theories suggest that the capacity to reach systematic patterns of emotion component activities and the sensitivity of such patterns to the context of the organism results from evolution. The patterns are neither arbitrary (as in psychological constructionism) nor organized by an affect program (as in basic emotion theory) or by a particular emotion component (as in appraisal theory). Instead, they are self-organized. Furthermore, the contexts are not general themes (such as threat in basic emotion theory), but refer more subtly to the organism's previous state in combination with the relation of the organism to its current environment. The perception of dynamics and their contingencies, as well as the ability to integrate such information in self-organized attractor states, has evolved (Fogel et al., 1992). Social pressures in interaction with ontogenetic maturation lead to the differentiation and integration of the emotion components to specific attractor states (Camras, 2011). The interaction between a context and maturation may be similar across cultures and results in the appearance of similar emotion attractor states.

To summarize, basic emotion theories propose that basic emotions have evolved, appraisal theories suggest that links between appraisals and other emotion components are universally shared, psychological constructionist theories argue that only subjective feeling (core affect) results from evolution, and nonlinear dynamic systems theories propose that evolution led to sensitivities for dynamics and contingencies.

How Should the Emotion Space Be Described?

A fourth controversy concerns the characterization of the relation among emotions. Basic emotion theories propose that emotions are discrete events. These theories identified between 3 and 11 discrete basic emotions (e.g., joy, sadness, and anger). Other emotions are seen as variants within an emotion family (e.g., Ekman, 1992), as mixtures of the more basic emotions (e.g., Plutchik, 2001), or as other types of emotions (e.g., emotion schemas; Izard, 2007). Systematic relations between discrete emotions have been proposed (e.g., Plutchik, 2001).

Appraisal theorists suggest that emotions are structured on the basis of an underlying appraisal space. Appraisals are commonly viewed as continuous (but see Roseman et al., 1996) and contain relevance appraisals and additional appraisals such as agency and coping potential. For example, the component process model (e.g., Scherer, 2009) has 14 appraisal dimensions. The resulting appraisal space contains an unlimited number of emotions, but researchers often focus on 'modal' patterns of emotion components that occur with greater frequency in human interaction and are labeled with commonly known emotion terms (e.g., happiness, anger). Given the large appraisal space, emotions are not typically represented in terms of appraisals only.

Similar to appraisal theorists, psychological constructionist theorists propose the existence of affective states that do not conform to the common component patterns described in natural language; however, the underlying dimensions are seen in core affect and not in appraisals. Focusing on the valence and arousal dimension, psychological constructionists build on dimensional models that date back to Wundt (1897).

However, the valence and arousal model is not applicable to the assessment of mixed emotions. As an alternative to describing emotions on a bipolar valence dimension (i.e., positive–negative), others have therefore proposed a bivariate valence space with independent positive and negative dimensions (e.g., Larsen and McGraw, 2011).

Similar to appraisal theories, nonlinear dynamic systems theories suggest that an unlimited number of emotion component patterns are possible and that some are more likely to occur than others (these are the so-called attractor states; Camras, 2011). Furthermore, control parameters determine whether the relation between input and output is linear or not. As a result, the relation between emotions may be linear at some levels of the control parameter, but show abrupt phase shifts at other levels of the control parameter. The structure of the emotion space is therefore described in relation to control parameters.

To summarize, basic emotion theories characterize the emotion space by discrete emotions, appraisal theories propose

underlying appraisal dimensions, psychological constructionist theories describe underlying valence and arousal dimensions, alternative dimensional theories propose independent positive and negative valence dimensions, and nonlinear dynamic systems theories characterize the emotion space in relation to specific control parameters.

Complementarities of Different Perspectives

To some extent, the alternative views about emotions proposed by different schools of thought can be reconciled. Furthermore, it can be argued that in focusing on different research agendas, the competing emotion theories have led to distinct insights that result in a broader understanding of the complex mechanisms underlying emotional reactions.

The Emotion Space as a Coin with Two Sides

With regard to the emotion space, in particular, the discrete and dimensional approaches taken by basic emotion theorists, appraisal theorists, and psychological constructionist theorists do not necessarily contradict each other (Izard, 2007; Scherer, 2005). For example, discrete emotions can be projected onto a dimensional model, such as Russell's circumplex model (see Russell, 2003). Indeed, researchers often aggregate discrete emotions on the basis of superordinate dimensions, factors, or clusters. Based on a new semantic profile analysis of emotion words (GRID; Scherer, 2005), Fontaine et al. (2013) found that the emotion domain can be represented from the perspectives of both emotion components and emotion dimensions and furthermore, that each of these perspectives lead to unique insights. For example, the dimensions underlying the subjective feeling component most closely resemble the dimensions underlying all emotion components jointly (i.e., valence, power, arousal, novelty; in that order of importance), whereas the dimensions underlying the physiological component are rather different. Based on this study, a self-report measure of emotions that reflects a combined discrete and dimensional approach has been refined (Geneva Emotion Wheel; Scherer et al., 2013).

Complementary Bodies of Knowledge about Emotions

The bodies of knowledge that have been generated by proponents of different emotion theories add specific insights to our understanding of emotions. Basic emotion researchers focus on the adaptive function of an emotion and examine continua across phylogenetic and ontogenetic development. In much of this work, scientists examine emotion expression and perception. An example of the research knowledge gained from this focus is that enacted expressions of happiness, anger, sadness, fear, disgust, and surprise are similarly perceived across cultures (e.g., Ekman, 1992). Also, differences between natural and simulated emotion expressions (e.g., in deception) have been identified.

Appraisal theories focus on the process that leads to an emotion. Researchers have converged on a short list of the most important appraisals, namely, appraisals of novelty, valence, certainty, goal significance, agency, coping potential, and compatibility with norms (Ellsworth and Scherer, 2003). Further, studies have shown support for many of the proposed links between appraisals and subjective feelings, action tendencies, motor expressions, and physiological activities (e.g., Scherer, 2009). Underlying appraisals have proven useful to describe cross-cultural differences in emotion experience (Scherer, 1997).

Psychological constructionist theories focus on the construal of an emotion category. Scientists working within this research tradition have identified context factors in emotion categorization such as salient emotion terms and previously seen emotion expressions. They have sensitized researchers to the influence of response formats in the study of emotions (e.g., Russell, 2003). They also gathered evidence to further establish that the valence dimension explains the most variance in the classifications of affective stimuli and experiences (e.g., see review in Barrett, 2006).

Nonlinear dynamic systems theories focus on the context-dependent temporal dynamics within emotional states and on the dynamics between emotional and nonemotional states. Researchers have found that throughout ontology, emotional components are increasingly differentiated and integrated to attractor states in relation to particular contexts (e.g., Camras, 2011; Fogel et al., 1992). Studies have been conducted to identify the temporal dynamic of the attractor state for specific emotions (e.g., Hoeksma et al., 2007), and researchers have examined phase shifts between attractor states (e.g., in emotion perception; Sacharin et al., 2012).

Future Directions

The four questions posed above (Sections What Are the Respective Roles of and the Interrelations between Emotion Components?, How Are Emotional Episodes Distinguished from Nonemotional Episodes?, To What Extent Are Emotions Influenced by Evolution and Sociocultural Contexts? and How Should the Emotion Space Be Described?) have been extensively discussed by emotion researchers in the past. These questions concern the very nature of emotion and they remain central to the field. Future research will therefore continue to address, and disagree, about these issues. There is a tendency toward more integrative approaches that acknowledge the need to take into consideration many different aspects of the emotion process. In particular, the need to examine the appraisal of emotion-eliciting stimuli and situations is now widely recognized, although there is continuing debate about the causal role of appraisals in terms of changing other components. Similarly, few emotion researchers would deny that the conceptual knowledge of emotion categories plays a major role in verbal labeling, and that this process is strongly influenced by cultural and linguistic factors. However, because emotion processes in daily life are only rarely clearly categorized and labeled with an emotion term, many emotion researchers question the utility of emotion 'construction' based on purely conceptual grounds.

A more recent development in emotion research is an increased research focus on previously understudied types of emotions such as aesthetic emotions (e.g., rapture during listening to music), epistemic emotions (e.g., wonderment

about a scientific breakthrough), and different types of positive emotions (e.g., gratitude, love, pride). These types of emotions differ from the more commonly studied set of negative emotions (anger, fear, disgust, sadness) in that associated action tendencies – other than maintaining attention and approach tendencies – cannot be easily recognized. Researchers from the growing field of positive psychology have identified the utilitarian value of positive emotions by studying their long-term outcomes, for example, for health and life satisfaction (Fredrickson, 1998). A convincing functional account of aesthetic emotions has yet to be proposed.

Additionally, researchers are increasingly paying attention to the social functions of emotion. Thus, in addition to studying emotions at the individual level, emotion scientists are developing the tools needed to study emotions in complex social contexts. This includes research on the influence of culture and social class on emotional experiences, on emotions in social media, and on emotions in interpersonal interaction (e.g., von Scheve, 2013).

Furthermore, neuroscience has a strong influence on emotion research and led to the institutionalization of the affective neurosciences (Panksepp, 1998). Many affective neuroscientists have started to abandon the quest for emotion-specific brain structures and increasingly examine emotion processes in the brain by identifying the circuitry underlying dynamic processes. Affective neuroscience provides new input for emotion research regarding the emotion mechanism as it provides new tools for the precise measurement, for example, with respect to the sequence and timing of appraisal processes (Gentsch et al., 2013; van Peer et al., 2014).

The neuroscience turn in emotion research is part of a general trend toward an increased reliance on interdisciplinary approaches to examining emotions. The new field of affective sciences (see Davidson et al., 2003; Sander and Scherer, 2009) brings together psychologists, biologists, clinicians, neuroscientists, philosophers, linguists, lawyers, historians, and economists. Very recently, the affective sciences have been extended to include engineers and computer scientists studying affective computing, which includes computer recognition of emotion and modeling of artificial emotions through avatars (see Scherer et al., 2010). This development allows researchers to study emotions in novel ways that have hitherto been impossible (e.g., due to ethical concerns). The field of affective sciences provides, for the first time in the history of emotion research, the theoretical constructs, and the methodological tools required for the comprehensive study of the phenomenon.

Abstract

Since its introduction some 30 years ago, sociological interest in the study of emotion has flourished. Today, it is no longer necessary to defend the role of emotion in social life. Indeed, emotions and their consequent processes have become recognized not only as relevant, but also as crucial to many – if not all – levels of society. Sociological scholarship on emotion includes a range of topics, including, but certainly not limited to, the role that feelings play in face-to-face interactions, mental health, identity maintenance, group processes, the creation and reification of stratification hierarchies, social change, social movements, and time.

Introduction

Prior to the formal development of the sociology of emotion, emotion had, historically, been left to the purview of psychologists. With few exceptions, psychological scholarship on emotion has focused more closely on cognitive and neurological processes as predictors of emotional experience than it has on the social environments in which individuals are embedded. In particular, psychologists have concerned themselves with how emotions relate to cognition and personality and, to a lesser degree, social and physical health, without taking into consideration the degree to which every aspect of emotion – from its initial constitution to its consequence – are profoundly social (see Lewis et al., 2007 for a recent review of the field). Over the last three decades, however, sociological scholarship on emotion has begun to fill this gap. That is, sociological observations reveal that feelings are not only social constructs, but also socially patterned and play a vital role in social life.

At their most basic, sociological definitions of emotion reveal the assumption that emotions are inherently social. Hochschild (1983), for one, likens emotions to senses that signal what is personally relevant about surrounding events. Similarly, Lively and Heise (2014) have defined emotion as responses to events that are linked with corporeal manifestations. Consistent with both these definitions, is Thoits' (1990) four-factor model of emotion. Building off the classic two-factor model of emotion first developed by Schachter and Singer (1962), which included physiology and cognition, Thoits' analyses suggest that emotional experience also includes expression (Ekman, 1973) and emotion words (Ritchie and Barker, 2006). Notably, each of these four factors – that is, physiology, cognition, expression, and labeling – are interdependent and most sociologists assume that a change in one may lead to a change in the others, suggesting multiple pathways for emotion management.

Origins of the Sociology of Emotions: 1975–85

Particular emotions were, indeed, important to classical sociologists (Marx and alienation, Weber and disenchantment, Durkheim and anomie, etc.). Their treatment, however, was not concerned with the light they shed on the broader social–emotional process in general (Smith-Lovin, 1995).

It was not until 1975 that American sociologists called for a study of emotion as a social process in its own right. In that year, Arlie Hochschild (1975) argued that a purely cognitive view of human life was not sufficient for sentient humans. Her insistence that emotion was socially patterned was partly explained by her concept of feeling rules, i.e., culturally and historically variable norms defining what should be felt in various situations. Her conceptualization of 'emotion work' described the individual processes that maintained these norms, which occurs when actors experience a discrepancy between what they actually feel and what they should feel. Techniques used to change emotions include surface acting to mask or enhance the expression of emotion and deep acting wherein the actual emotion is changed.

Although Hochschild focused primarily on the cognitive strategies that individuals used to accomplish deep acting, later studies suggest that emotion-management specialists (that is therapists (Francis, 1997), psychodrama leaders (Thoits, 1995), and social movement activists (Britt and Heise, 2000)) also use interpersonal emotion strategies to manage the emotions of others directly. Many of these interpersonal strategies target one or more of the four factors in Thoits' model of emotion – as detailed above – simultaneously (also see Simon and Nath, 2004).

Taking a more positivist approach to the study of emotion, Kemper's (1978) social interactional theory argued that two fundamental dimensions – power and status –determine all emotions across a variety of social contexts. Drawing on Weber's classic definitions, 'social power' refers to one's ability to force another's compliance against their will, whereas 'social status' refers to favors freely given. When individuals experience the levels of status or power they expect during the course of a social interaction, they are predicted to feel content or happy. Experiences of excesses or deficits along these dimensions, however, automatically produce certain distressful emotions depending on whether one attributes the cause to one's self or others as well as the relationship between actors. For instance, if an individual loses status, as a result of his or her incompetence, embarrassment is expected. However, if he or she loses

status as a result of another's actions, anger is the expected response. These predictions are conditioned further depending upon the degree that the other is well liked.

At the same time that Kemper was developing his somewhat deterministic model, Shott (1979) introduced an interactionist view of emotion that stressed the importance of emotion in social control. According to the interactionist perspective, role taking is the capacity to see oneself as do others and to use their anticipated response as a guide to further conduct. Although Mead's (1967) discussion of role taking was almost entirely cognitive (MacKinnon, 1994), Shott, like Hochschild before her, argued that cognition, alone, was not enough to motivate and to sustain normative social control. However, role-taking emotions, such as embarrassment, shame, guilt, as well as other directed empathetic emotions of sympathy and pride could. She suggests that individuals' desire to avoid negative emotions (including shame and embarrassment) and to experience positive ones (such as pride and empathy) encourages them to engage in self-control, which translates, writ large, into social control.

By 1985, the sociology of emotions was formally recognized as a subsection in the American Sociological Association. Since that time, there have been numerous reviews of the field (Thoits, 1989; Smith-Lovin, 1995; Turner and Stets, 2006), including two full-length handbooks (Stets and Turner, 2014) and a series of volumes dedicated to social perspectives on emotion (e.g., Franks and Gecas, 1992). During this same period, several social psychological theories within sociology were also expanded to make considerations of emotion more central (Smith-Lovin, 1990; Ridgeway and Johnson, 1990; Lively and Heise, 2014; Stets, 2005; Lawler and Thye, 1999; Lively et al., 2010; Hegdvedt and Parris, 2014; among others).

Cultural Shaping of Emotion

Today there is little debate that certain cultures encourage and discourage certain emotional experiences, which lead to important behavioral dispositions. In her seminal work on sympathy in everyday life, Clark (1997) begins by describing the Ik, a tribal community known for their marked lack of sympathy. Given their propensity to laugh when older group members fall down or to simply watch when an unattended child walks toward an open fire, the Ik provide a stark contrast to most Western cultures, whose members are, for the most part, sympathetic toward the elderly and children or others whose misfortunes seem largely beyond their control.

Clark's analysis of the US emotion culture details a sympathy economy, under which individuals are automatically granted a certain amount of sympathy (known as sympathy margins) that are, in large part, a function of their age, gender, social class, etc. As individuals move through daily life, they draw upon – and invest in – these accounts by asking for and providing sympathy to others. Clark identifies four sympathy rules to which individuals are expected to adhere in order to avoid becoming overdrawn; these include not making undue claims to sympathy, not asking for too much sympathy, asking for some sympathy, and reciprocating once sympathy has been received, either by providing sympathy to your sympathizer when necessary, being sympathetic to others, or simply expressing gratitude.

Historical accounts of various emotions also illustrate not only how feelings, and expectations regarding them are culturally patterned, but also how they change over time (Stearns and Stearns, 1989; Stearns and Lewis, 1998). Content analyses of self-help books and women's magazines, for example, reveal that the emotion norms – particularly those surrounding love and anger – have changed considerably for wives over the last several decades (Cancian and Gordon, 1988). Additionally, love in the United States has grown increasingly feminized; despite heterosexual couples' move toward more egalitarian/androgynous gender roles (Cancian, 1987; Gerson, 2010).

Other examples of the cultural shaping of emotion include the literature on gender and emotion, leading some scholars to argue that there are distinct emotion cultures for women and men (Simon and Nath, 2004). Important here is the devaluation of emotion (as irrational or unprofessional, for example) and the belief that women are inherently more emotional than men. Such beliefs routinely disadvantage women in the workplace or cause their labor at home to remain largely invisible. Recent survey research suggests that there are actually very few differences in the self-reported emotional experience of women and men once structural considerations are accounted for; however, differences in self-reported expressions of emotion persist (Simon and Nath, 2004).

Scholars have also turned their attention to how race and ethnicity shape emotional experience and expression. Qualitative studies of historically white organizations and occupations reveal that African-Americans often encounter different emotion rules than their white peers and that they are keenly aware of the necessity of avoiding racial stereotypes, particularly those involving the experience and expression of anger (Harlow, 2003; Wingfield, 2010).

Studies of subcultures are also instructive. Individuals participating in a polyamorous community, for example, have created their own language as a way to dispel disruptive feelings and to create a deeper sense of community. Indeed, in a subculture where jealously is looked down upon, members are encouraged to use less emotionally charged words to describe their feelings, such as 'wibbly.' Similarly, polyamorists also have words to describe the love they feel for their partners' lover, another concept that has no real meaning in societies where monogamy is the hegemonic ideal. Similarly, fans of jam bands, such as the Grateful Dead and Phish have developed different emotional cultures, particularly regarding such social identities as narcotics agents and law enforcement officials (Hunt, 2008, 2013).

Structural Shaping of Emotion

Emotional experience, as well as its expression, is also shaped by structure or, to put it a different way, status. The literature on gender and emotion and race and emotion are useful here as well.

In her now classic work, *The Managed Heart: The Commercialization of Human Feeling*, Hochschild first introduced the

notion of 'status shields,' i.e., shared interpretive dispositions that protect those of privilege against (1) the displaced feelings of others, (2) the negative interpretation of one's own emotional expressions, and (3) the conviction of others that one's emotions are unwarranted and unimportant. The undermining of women's anger by interpreting them as 'crabby' because of their menstrual cycle or otherwise 'hysterical,' just as undermining African-American men's anger as a function of being 'an angry Black man,' are obvious examples of a structured lack of status shield. The aggregate of such interpretations serve white male dominance, not only in the workplace, but also at home and in small task-focused groups, such as juries.

Emotions are also shaped by the ways whole societies are organized, as well as the organizations within them. For instance, Hochschild and Machung, 1989 demonstrated how macrolevel changes in women's entry into the workforce affected microlevel gender imbalances in feelings of gratitude between couples in the household. Because of traditional gender roles, men's relatively small contributions to housework evoked more gratitude than the larger contributions from their working wives. This resulted in a 'second shift' for women and interpersonal tension within the couple. Drawing on her previous ideas of emotion work, Hochschild argued that husbands and wives cocreated elaborate family myths as a way to bridge the gap between their own gender ideologies (that is, traditional, transitional, and egalitarian) and the household arrangements within their marriages. These 'myths' tended to obscure ongoing inequities, as well as challenges to individuals' identities as feminist, egalitarian, or, in some cases, breadwinners. Scholarship in this area is likely to prove fruitful going forward, as many women – particularly those in the working class families – now outperform their male partners in terms of education, labor market participation, and wages (Rosin, 2012).

Although emotions have historically been viewed as antithetical to rational behavior and professionalism, businesses and organizations have become increasingly adept – unwittingly as well as consciously – at organizing emotional processes. While most accept that feelings can impede organizational efficiency, it is also true that they are necessary for organizations to operate effectively. Any workplace must encourage loyalty and manage disenchantment, stirrings about power, status, and justice; anxieties about keeping control and being controlled; pride; defensiveness; fear of change; and the comforts of the familiar.

Emotional labor, according to Hochschild (1983), is the commercial exploitation of the principle of emotion work (see above). The flight attendants she studied were paid to 'be nice' regardless of insults and paradoxically asked to be genuine. Bill collectors, on the other hand, were taught to be angry, mean, and impatient, in order to bring about fear and compliance in debtors. Unlike 'emotion work,' which typically occurs in individuals' private lives (such as trying to feel sad when one has adopted the role of mourner or trying to feel happy when one has adopted the role of bride) and has a 'use value,' 'emotional labor' is sold for a wage and typically benefits the corporation by whom the actor is employed or the customers, clients, or patients with whom the actor is engaged. Since its introduction, there have been numerous studies attempting to determine the socioemotional effects of providing emotional labor (Wharton, 2009).

The emotional labor necessary of students (Cahill, 1999; Smith and Kleinman, 1989), fast food workers and insurance salesmen (Leidner, 1993), amusement park employees (Van Maanen and Kunda, 1989), male and female rescue workers (Lois, 2003), Korean nail salon owners (Kang, 2010), professors (Bellas, 1999; Harlow, 2003), mixed martial arts fighters (Vaccaro et al., 2011), home health care aids (Stacey, 2011), health care providers (Erickson and Grove, 2008), direct home sales consultants (Mullaney and Shope, 2012), homeschooling mothers (Lois, 2013), and Black college men (Jackson, 2013), among others, have all proved of interest to sociologists interested in the nuances, as well as the consequences of, emotional labor.

Emotional Deviance and the Emotions of Deviants

In addition to studying how culture and social structure shapes emotional experience and behavior, sociologists are also interested in the ways in which individuals – and their emotions – deviate from cultural and structural expectations. To date, deviance – or the inability or unwillingness to adhere to societal expectations – has been dealt with in two ways. The first refers to emotional deviance (Thoits, 1989); the second refers to the emotions of those individuals who hold deviant, or stigmatized, identities (Lively and Heise, 2014).

In an attempt to better understand the relationship between emotion and mental health problems, Thoits (1990) coined the term 'emotional deviance.' Building on Becker's (1963) labeling theory of deviance, Thoits argues that individuals are often labeled – by self and others – as mentally ill, as a result of their inability to bring their emotions in line with preexisting emotion rules or norms. According to this perspective, sources of discrepant feelings include multiple roles, role transitions, and unrealistic role demands. Individuals who self-label as emotionally deviant are increasingly likely to seek professional help, despite the historical stigma associated with mental illness. In this regard, Thoits' analysis drew attention not only to the emotional dimensions of coping behaviors and social support but also the effect of the deinstitutionalization of mental health care on individuals' willingness to voluntarily seek help for emotional issues. Since its introduction in the late 1980s, the concept of emotional deviance has been applied to numerous populations, most often to mothers (Taylor, 1996; Lois, 2013).

More recently, scholars have also begun examining the emotions of deviants – that is, individuals who hold socially devalued or otherwise stigmatized social identities, such as rapist or murderer. Based on computational models, Heise found that the experience of positive emotions do not benefit those with stigmatized identities to the same degree as they do those with socially valued identity. For example, a happy mother is viewed as much nicer than a mother who experiences or expresses no affect, whereas a happy rapist is viewed only as slightly less negative than a rapist who appears affectively neutral (Lively and Heise, 2014). Further analysis suggests that extremely negative role identities, such as rapist, mugger, child molester, etc., are also more emotionally volatile than those that are less negative. Future scholarship – perhaps

qualitative or ethnographic in nature – may be useful in better understanding the emotional lives of society's most stigmatized members.

Identity, Emotion, and Social Structure

According to sociologists, one's sense of self, or one's identity, is connected to social structures and institutions (MacKinnon and Heise, 2010; also see Stryker and Serpe, 1994, 1992; Burke, 1991). This is, in part, because identities are embedded in social roles. According to most theories of identity, emotions help determine what roles are chosen as central to how one sees oneself. Emotions affect role performance (e.g., confidence may propel us forward, whereas fear may cause us to choke). Emotions also arise from role performances (e.g., pride when things go well or shame when they do not).

The emotional aspects of identity work are, in effect, commitments to role performances. That is, when actors conform to the emotional and behavioral expectations of social roles they are not only managing their sense of self, but they are also reifying the institutions and organizations in which these roles are embedded. For example, when individuals enact the emotional and behavioral expectations of a physician, they are also reifying the institution of medicine. They are also perpetuating the relative status positions of physicians and patients and physicians and other health care providers.

According to affect control theory (ACT), individuals create events that confirm their fundamental affective sentiments regarding themselves, others, and settings (Heise, 2007). Moreover, when they find themselves in situations that disconfirm these sentiments, they feel deflection, which is often experienced as emotion. Fundamental sentiments capture evaluation (how good or bad something is), potency (how powerful or weak something is), and activation (how lively or quiescent something is); these dimensions of affective meaning have been documented across numerous cultures and, within a single culture, represent shared meaning regarding identities, behaviors, settings, attributes, and emotion Heise 2007). Drawing on a cybernetic model, ACT predicts that when transient sentiments contradict fundamental sentiments, individuals are motivated to alter their behavior in order to minimize deflection and reduce the likelihood of reidentification of self, other, or both.

Much of the theoretical work within the sociology of emotion has been based on qualitative methods, such as ethnography and in-depth interviews. In contrast, ACT incorporates a unique computer program – Interact – that uses mathematical models in order to make probabilistic predictions regarding behaviors, emotions, and labeling, many of which have been replicated using ethnography, survey data, and experiments (Francis, 1997; Lively and Powell, 2006; Robinson et al., 1994).

Although ACT was initially developed as a theory of identity, where emotions were essentially a signal of the degree to which one's identity was being confirmed or disconfirmed during a course of daily interaction, emotions have become increasingly more central. Lively and Heise (2014) recently summarized the contributions of ACT to the sociological literature on emotion and have suggested a number of new avenues of ACT-based scholarship in emotion, including emotional segueing (Lively and Heise, 2004; Lively, 2008), emotional stations (Lively and Heise, 2004; MacKinnon and Heise, 2010), and the cross-cultural absence of emotions that can be viewed of as simultaneously positive, weak, and active. Rogers et al. (2014) have suggested that ACT may provide long-overdue launching point for cross-disciplinary collaboration on emotion because of its empirically grounded conceptualization of social mechanisms operating at the level of interaction, relationship, and culture, as well as its specification of processes linking social and individual aspects of emotion.

Identity control theory, as articulated by Burke and Stets (Burke, 1991; Stets, 2005), also illustrates that emotions are implicated when individual's identities are disconfirmed. Unlike ACT, which calculates deflection using culturally shared affective meaning of social roles, behaviors, and settings, identity control theory is focused primarily on the correspondence between individuals' self-conceptions and others' reactions to their identity performances.

While both identity control theory and ACT assume that emotions result from identity processes, there is some disagreement as to what forms these emotions will actually take. Regardless, identity control theory also predicts that individuals are motivated to bring others' reactions to their identities in line with their own. Burke and Harrod's (2005) analysis of identity processes among intimate couples, for example, reveals that individuals within committed relationships are more content when their partner's evaluations of them match their own, compared to individuals' at the beginning stages of relationships, who would rather their partners' see them as slightly better than they see themselves.

Emotion and Equity, Justice, and Exchange

Other social psychological theories – including equity theory (Walster et al., 1978), justice theory (Hegdvedt and Parris, 2014), and exchange theory (Lawler, 2001; Lawler and Thye, 1999) – also detail the coconstitutive relationship between emotion and social structure.

Equity theory, for instance, predicts that individuals are also likely to experience negative emotion when they perceive an inequity in their interactions with others. Originally, the theory predicted that individuals would experience ungeneralized distress, whether they were underbenefited or overbenefited. However, later scholars specified that anger was more likely in the former case, whereas shame was more likely experienced in the latter.

Most of the early scholarship on equity and discrete everyday emotion was based on experiments, based on college student samples. Later survey-based studies of married and cohabitating adults, however, found that a broad range of emotions – including positive ones – are affected by perceptions of inequity within the context of long-term romantic relationships. Further, in the case of the household division of labor, men were more likely to experience anger and rage when faced with perceptions of under benefiting (that is, doing more than their fair share), whereas women were more susceptible to feelings of self-reproach and fear when confronted with

perceptions of overbenefiting (that is, doing less than their fair share). These findings suggest that women may willingly do more than their fair share of the household division of labor in order to manage their own – and their male partners' – negative feelings. Needless to say, such endeavors – while the managing unpalatable emotions of both self and other – do little to ameliorate the conditions that arise to perceptions of inequity in the home that led to these emotions to begin with.

The justice framework also has grown to include the study of emotion (see Hegdvedt and Parris, 2014, for a complete review). Justice theorists generally consider two processes: procedural justice and distributive justice. The former focuses on the means by which outcomes are distributed, whereas the latter is more concerned with the actual allocation of outcomes, often taking into account such issues as need, equity, and equality. Generally speaking, people are happy when they feel like procedural decisions are just and the outcomes seem fair. They are less sanguine, however, when they believe the procedures to be unfair and the outcomes – as a result – fail to meet their expectations. Indeed, most people assume that fair procedures will lead to fair outcomes. However, even when individuals experience less than they expected, their negative feelings are somewhat alleviated, if they believe the procedure governing the decision is fair (Hegdvedt and Killian, 1999) or if the decision maker is legitimate (Clay-Warner, 2006).

Finally, exchange theorists, too, have been making advances in conceptualizing the role of emotions in exchange interactions. A framework for a number of more specific theories (e.g., the theory of social commitments (Lawler et al., 2009), relational cohesion theory (Lawler and Yoon, 1996), and the affect theory of social exchange (Lawler, 2001)), exchange theory, at its most basic, suggests that individuals who perceive equity in their social arrangements, who see these arrangements as inherently just, and who believe that their contributions are successful, are not only happier with their outcomes, but also experience more group cohesion and are more affectively committed to participate in ongoing exchanges. Conversely, individuals who feel that their costs outstrip their rewards, their contributions are not valued, or the exchange is not successful are likely to exit the exchange – whether within the context of a friendship, a marriage, or a job, or a small task-focused group – especially in light of better viable alternatives.

Taken together, these social psychological perspectives reveal that emotions are shaped by existing social and structural arrangements. They also illustrate emotions' ability to contribute to – and disrupt – the very conditions that gave rise to them initially. Equity theory, justice theory, and exchange theory all rely on the assumption that it is the perception of equity, fairness, or net gains over the course of a single – or ongoing – interaction that affect emotions, rather than the actual, obdurate conditions in which the individuals are actually embedded.

Emotions and Social Change

Emotions have always been recognized as part of social movements (Goodwin et al., 2001). Until the 1970s, emotions were viewed as essential to movements but were, nonetheless, viewed pejoratively – that is, as something that transforms protestors into angry, irrational mobs. Then, from the 1970s to the 1990s, scholars routinely overlooked the emotions of protesters – mainly out of fear that documenting strong emotions would paint the protestors as irrational – as opposed to rational – actors. It was not until the 1990s – bolstered by the rise of cognitive-appraisal theories – that emotion began to reappear as a normal part of political action (see Jasper, 2014).

Since making emotions more central, social movement scholars have identified several emotional dynamics that help explain social and political protest. These include acts of persuasion, motivations for action, the solidarities of groups, the impact of morality on political action, and the gendered division of labor in social movement organizations.

In addition to the role that emotions play in social movements (e.g., pride or righteous anger), scholars have also turned their attention to the role that emotion management – particularly interpersonal emotion management – plays in motivating social movement participation. Identity-based social movements face a unique challenge in motivating potential constituents to participate in collective action (Britt and Heise, 2000). Because identity-based movements often involve stigma, and thus shame, constituents may wish to limit their involvement. As such, inspiring individuals to take action can be challenging. According to Britt and Heise, movement activists use identity-based emotion-management strategies that maneuver constituents through fear and anger in order to get them from an affective space largely characterized by shame and into one of pride. When potential constituents feel pride (a relatively positive, powerful, and active emotion), they are more likely to participate in positive, powerful, and active behaviors, such as social protest, marching, chanting, etc. (Also see Taylor, 1996.)

Gould's recent analysis of the rise, success, and eventual decline of ACT UP (AIDS coalition to unleash power) organizations during the beginning of the US acquired immune deficiency syndrome (AIDS) epidemic documents the role of both emotion and emotion management in creating and sustaining social change (2009). According to Gould, the gay and lesbian community actively encouraged members to feel and express anger toward the federal government following a Supreme Court decision that upheld a state ruling deeming homosexual sodomy in the privacy of one's own home illegal. The successful transformation of the groups' collective shock and grief that had arisen during the early years of the AIDS epidemic into anger and rage after the Supreme Court decision resulted in the proliferation of ACT UP organizations across the country, which led to both short-term upheaval and long-term social change. Gould's analysis suggests that in order for emotions and, subsequently, protest to ignite, a certain emotional habitus – that is, a template for what and how to feel – is necessary. Prior to the Supreme Court decision, the gay and lesbian community was lacking such a template that would not only allow, but also encourage, its constituents to feel anger and to engage in sustainable protest.

Emotion and Time

Over the last decade, emotion scholars have become increasingly interested in time. To date, sociologists have utilized three

approaches when thinking about how time influences emotion and emotion management.

The first approach, which deals specifically with emotion, has to do with how time – usually the shortage thereof – gives rise to certain feelings. Family scholars in particular have documented how a marked lack of time leads to an increase in negative affect and decreased familial satisfaction, particularly for women who routinely have less 'leisure' time compared to men (Hochschild and Manchung, 1989).

The second approach, which deals more with the temporality of emotion management, speaks to issues of timing – that is, how emotion management unfolds before, during, and after a triggering event (e.g., participating in a search and rescue mission (Lois, 2003), passing as a member of the opposite sex (Schrock et al., 2009), or engaging in mixed martial arts (Vaccaro et al., 2011)).

The final approach, also dealing with emotion management, reveals how individuals purposefully manipulate their own sense of time in order to manage their emotions. Homeschooling mothers, for example, purposefully focus on the fleeting nature of childhood or focus how much they are going to miss homeschooling once their children are grown so that they can more easily appreciate the present (Lois, 2013). The Home Direct Sales industry, among others, have also gotten very sophisticated at managing time in order to generate enthusiasm and loyalty among their consultants (Mullaney and Shope, 2012).

Empathy: A Social Neuroscience Perspective

Jean Decety and Greg J Norman, The University of Chicago, Chicago, IL, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

The concept of empathy is applied to various phenomena which cover a broad spectrum ranging from experiencing emotions that match another individual's emotions, feelings of concern for other people and knowing what the other is thinking or feeling. This conceptual diversity explains the difficulties in measuring empathy. None of the attempts to quantify it with self-reports, peer ratings, or rating scales of observed behavior have been able to capture the entire range of affective, cognitive, and behavioral components of empathy. In this article, we will expound that human empathy is better understood with reference to the phylogeny of the social brain. Empathy has deep evolutionary, biochemical, and neurological underpinnings. Even the most advanced forms of empathy in humans remain connected to core mechanisms associated with affective communication, social attachment, and parental care. Empathy is mediated and moderated by multiple physiological and brain systems as well as social context. Finally, drawing from patients–doctor relationships in medicine, we will show that empathy is adaptive for oneself and for others.

Empathy—the natural capacity to share and understand others' feelings and thoughts—plays a pivotal role in human social interaction. Empathy-related processes motivate prosocial behavior, inhibit aggression, and provide the foundation of moral reasoning. Empathy is such a necessary component of healthy coexistence that its absence leads to serious social-emotional dysfunctions, including psychopathologies such as psychopathy. Empathy and other prosocial behaviors have been a focus of speculation in philosophical, psychological, and physiological investigations throughout written history (Batson, 2009). However, over the last decade there has been an explosion of research into empathy and its underlying evolutionary, psychological, and neurobiological foundations that have taken the topic from the realm of philosophical speculation to the confines of rigorous scientific investigation (Mason & Ben Ami-Bartal, 2010).

In the present article, we propose that the topic of human empathy is best understood within the context of its underlying evolutionary, neurobiological, and psychological mechanisms. We will show that empathy has deep evolutionary, biochemical, and neurobiological underpinnings associated with affective communication, social attachment and parental care, characteristic of all mammals. Finally, drawing from research in medicine on patient–doctor relationships, we will expound that the application of current research into empathy has the potential to improve physician efficacy and patient outcomes.

Evolution of Empathy

Social species, particularly primates, are adapted to live in groups and their members are naturally driven toward establishing and maintaining social bonds. Adults who formed attachments would be more likely to reproduce and long-term relationships would increase the chances that the offspring would reach maturity and reproduce in turn. Empathy increases the inclusive fitness of organisms by enhancing survival in a variety of ways (e.g., providing increased defense against predators) and it serves to bond individuals to one another, especially mothers to offspring (Plutchik, 1987). Mammalian reproductive fitness and survival depend crucially on the ability of conspecifics to communicate with each other, sharing information about their affective and motivational states and appropriately responding to their allies and relative's needs. Importantly, empathy entails more than just understandings or expectations. When individuals empathize, they vicariously feel the emotions of others, which can promote affective communication and can motivate individuals to behave prosocially toward conspecifics (Decety, 2011).

The psychological and neurobiological components that underlie empathy and empathy-related processes have been conserved across evolutionary history and are apparent to some extent in all mammals. Indeed, the capacity for empathy in humans emerges from an elaboration and rerepresentation of functions apparent in other social mammals. Thus, the neurobiological substrates of empathy-related processes are present at many levels of the neuraxis. The rerepresentation of empathy-related processes allows for the rapid expression of empathic-like responses, such as orofacial mimicry, while simultaneously generating more elaborated emotional and cognitive empathy-related processes, such as perspective taking, that rely on dynamic interactions between limbic and cortical structures (Buchanan et al., 2012; Decety and Jackson, 2004; de Waal, 2008). Research in animals has shown that the capacity to share and be affected by the emotional state of conspecifics is generated by basic neurobiological systems subserving attachment-related processes, involving the brainstem, preoptic area of the thalamus, and paralimbic areas (Panksepp, 1998; Watt, 2000). As a result of the importance of social connections for mammalian survival, these attachment systems appear to exploit the well-developed physical pain system, borrowing the aversive signals associated with pain to indicate when relationships are threatened (Eisenberger, 2011; MacDonald and Leary, 2005). Therefore, just as the physical pain system alerts organisms to the presence of a noxious environmental stimulus and motivates them to rapidly escape the source of pain, so too does the social pain system; the experience of social pain alerts an individual to

potential threats in their social environment and can induce various coping strategies to attempt to mitigate the threat (e.g., increase motivation to strengthen relationships) (MacDonald and Leary, 2005). In addition to the pain system mentioned above, the dopaminergic reward system also appears to have been partially coopted for attachment and caring, and thus for empathic concern. Indeed, mammals are highly motivated to care for their offspring and experience this interaction as a highly rewarding experience (Mayes et al., 2009). Although empathy in humans is assisted by other general high-level cognitive abilities such as executive functions and language, which introduce contextual control and expand the repertoire of behaviors that can be driven by empathy and emotional connection, it also operates on more primitive reward processes and is highly dependent upon these lower level processes to achieve higher order goals associated with affective communication, social attachment, parental care, and motivation to cooperate.

Motivation to Care for Others

One likely source of empathic responses in mammals comes from the phylogenetically ancient practice of caring for one's offspring for extended periods of time that can be observed in other organisms (Cockburn, 2006; Goodwin et al., 1998). Mammals in particular have developed intricate parenting behaviors. These behaviors tend to take the form of large energetic investments in a fewer number of offspring. The ability to provide offspring with nourishment (i.e., lactation) and safety over long periods of time facilitates the development of more complex neurobiological and behavioral processes (i.e., social attachment) that improve the offspring's ability to pass on its genes into future generations. While there are clear advantages to this strategy, it also comes with significant risks. Indeed, this approach is less resilient to predation and disease as the loss of a single offspring has the ability to render the parental energy expenditure useless. In order to counteract this risk, mammals have developed a strong emotional attachment to their offspring that predisposes individuals to remain hypervigilant for potential threats thereby minimizing their risk of losing the ability to pass their genes onto future generations due to predation or disease.

The neurobehavioral manifestations of parental care also provide the means through which individuals within a social group are able to cooperate and care for one another. Kin selection models of social behavior presumes that the prosocial tendencies within groups resulted from the fact that organisms that assist their genetic relatives are better able to propagate a fraction of their own genetic legacy into future generations (e.g., assisting sibling's offspring which share 25% of one's genes) (Wilson, 1975). However, kin selection models of prosocial behaviors within groups do not actually specify how these behaviors are motivated and do not assume that individuals must be able to detect genetic relatedness (Bell, 2001). Thus, any evolved motivational system that increases the fitness of kin will produce the same results in terms of fitness regardless of fact that this motivational system may also apply to nonrelatives (Bell, 2010). The ability to model the emotions of nonrelatives and react appropriately within in a social group would likely confer some fitness advantages (e.g., better able to communicate and detect distress in group members). For example, the motivational systems that may have originally been developed to care for offspring have likely been coopted and used in the service of facilitating positive relationships between unrelated group members. In humans for example, our relationships with spouses, friends, and coworkers are highly valued and require vast amounts of psychological resources to maintain. In fact, the perception that such relationships are threatened engenders profound emotional and physiological stress responses (Norman et al., 2012a). Conversely, feeling well connected with friends and family provides a strong behavioral and physiological buffer that can diminish stress responses (Uchino et al., 1996). Therefore, while the motivational components of prosocial behaviors such as empathy may have originally developed in service of parental care, they have now become invaluable tools for the formation and maintenance of strong social bonds between unrelated individuals who provide the foundation for much of our successes as a social species. Importantly, the evolution of a caregiving system has produced social preferences. Kin selection and group selection may have occurred as an outcome of the evolution of a caregiving system.

Neuroevolution of Empathy-Related Behaviors

At the behavioral level, empathy-like responses can be observed in numerous species, for example, mammalian and avian species. For instance, the presence of specific behavioral (e.g., decreased preening behavior) and physiological (eye temperature) changes in hens observing their chicks being exposed to a mildly aversive stimulus indicates a responsive capacity that is distinguishable from the hens' own experiences of the same stimulus (Edgar et al., 2011). A number of empirical studies with rodents have demonstrated that affective arousal and emotional contagion can prompt efforts to alleviate the distress of a conspecific. For instance, rats that had learned to press a lever to obtain food stop doing so if their action is paired with the delivery of an electrical shock to a visible neighboring rat (Church, 1959) and rats will press a bar to lower another rat suspended in mid-air (Rice and Gainer, 1962). Similarly, rats will work to free a cagemate locked in a restrainer even when social reward was prohibited (Ben-Ami Bartal, Decety and Mason, 2011). This latter study found that rats that were made to choose between liberating a cagemate or receiving a highly palatable food (chocolate), they typically chose to release their cagemate and subsequently share the chocolate. Furthermore, pain sensitivity in mice is modulated by the presence of other mice displaying pain behaviors (Langford et al., 2006). Interestingly, this relationship is conditional upon the identity of the target mouse such that observing pain behaviors in conspecifics only influences pain behavior when the target mouse is their cagemate. Similarly, female mice show more freezing behavior when exposed to the pain of a close relative than when exposed to the pain of a more distant relative (Jeon et al., 2010). To investigate whether such pain behavior can serve the function of soliciting a primitive

form of empathic concern, Langford et al. (2010) used a social approach paradigm to test mice in various dyadic or triadic conditions. Some conditions involved restrained mice that were in pain as a result of intraperitoneal injection of acetic acid and test mice free to approach or avoid the restrained mice. Results revealed a gender-specific effect whereby female, but not male, mice approached a familiar same-gender conspecific in pain at higher rates than an unaffected familiar or unfamiliar, but affected, conspecific. These results can be interpreted as evidence of an effect of social support on the experience of pain, a finding consistent with human literature. Indeed, the presence of an individual who provides passive or active support reduces experimental pain in humans (Brown et al., 2003). It has been reported that perceived empathy of a partner can modulate subjective and autonomic responses to physical pain (Sambo et al., 2010).

Empirical reports of empathic reaction in apes indicate they too have an appreciation for the situation of conspecifics (Warneken et al., 2007). Primitive aspects of empathy, such as emotion contagion and parental care, have been clearly demonstrated in chimpanzees (de Wall, 2008). For example, an experiment in which peripheral skin temperature was measured in chimpanzees while they viewed an emotionally laden video demonstrated a decrease of skin temperature, indicative of sympathetic arousal, when they viewed videos of conspecifics injected with needles or videos of the needles themselves, whereas these changes were not observed when the chimpanzees viewed videos of a conspecific chasing the veterinarian (Parr, 2001). Thus, when chimpanzees perceive a conspecific exposed to painful stimuli, they show physiological changes similar to those observed in humans (Hatfield et al., 2009). Providing comfort to distressed conspecifics is an expression of empathic concern, and such other oriented behavior is now well documented in chimpanzees (Romero et al., 2010). Therefore, various social organisms display aspects of empathy and understanding of how these processes function in related animals provides an important insight into their role in human social behavior.

Neural Circuits Associated with the Perception of Others' Pain and Distress

The long history of mammalian evolution has shaped maternal brains (and paternal brains to a lesser extent) to be sensitive to signs of suffering in one's own offspring (Haidt and Graham, 2007). Even very young infants of 6 months of age are capable of preverbal evaluations when viewing social interactions. For example, babies are more likely to smile when viewing prosocial events, and to frown in response to antisocial events (Bloom, 2012). The earliest forms of empathic concern in humans appear between 8 and 16 months of age and continue to develop until adulthood (Roth-Hanania et al., 2011; Vaish and Warneken, 2012). In many primates and other mammals, this sensitivity has extended beyond the mother–child relationship; so all typically developed individuals generally find the suffering of others as aversive. Pain serves adaptive functions not only by warning the suffering individual, but also by impelling expressive behaviors that attract the attention of others that may provide assistance (Craig, 2009). Crying for instance is one prototypical attachment behavior. It is only an advantage to the extent that crying attracts a caregiver faster than it attracts a predator. Thus, pain can be considered an emotion triggered by the activation of a mental or neural representation of actual or potential tissue damage. This representation involves somatic sensory features, as well as affective–motivational reactions associated with the promotion of protective or recuperative visceromotor and behavioral responses. It is the affective experience of pain that signals an aversive state and motivates behaviors to terminate, reduce, or escape exposure to the source of noxious stimulation. Furthermore, the expression of pain also provides a crucial signal that can motivate soothing and caring behaviors in others (Jackson et al., 2005). Therefore, in addition to removing the potential threat, the expression of pain behaviors allows individuals to obtain assistance from other individuals within the group.

In humans, a number of neuroimaging studies have documented reliable activation of a neural network involved in the processing of pain, including the anterior midcingulate cortex (aMCC), anterior insular cortex (AIC), supplementary motor area (SMA), and periaqueductal gray (PAG) when individuals watch facial expressions of pain (Botvinick et al., 2005; Lamm et al., 2007) or body parts being injured (Jackson et al., 2005; Cheng et al., 2008; Decety and Michalska, 2010), imagine the pain of others (Jackson et al., 2006), or simply observe a signal indicating that someone will be hurt (Singer et al., 2004). It is worth noting that vicariously instigated activations of the pain matrix are not specific to the sensory qualities of pain, but instead are associated with more general survival mechanisms such as aversion and withdrawal when exposed to danger and threat (Decety, 2010). Of particular importance, the aMCC, a region that implements a domain-general process that is integral to negative affect, pain and cognitive control contains pain-responsive neurons that are activated by both anticipation of pain and instrumental escape from pain (Shackman et al., 2011). Activation of the AIC is nearly ubiquitous in studies of pain empathy: this response can even be elicited automatically as shown when participants viewed color photographs depicting human body parts in painful or nonpainful situations and performed either pain judgment (painful/nonpainful) or laterality judgment (left/right) of the body parts in the absence of explicit task requirements and attentional demands (Gu et al., 2010). The AIC and aMCC with the amygdala are parts of a salient network that segregates the most relevant among internal and extrapersonal stimuli in order to guide behavior (Menon and Uddin, 2010).

These findings demonstrate the ease with which an individual can integrate the physical and social pain of another into their own bodily somatic representation. Consistent with Jackson's notion of neuroevolutionary rerepresentation of function (Jackson, 1884), it has been proposed that the anterior insula, and its array of projections, serves to generate a higher order metarepresentation of primary interoceptive activity, which is related to the feeling of pain and its emotional awareness (Craig, 2007). These representations play an important role in the learning and adaptation of social behavior in addition to basic decision-making and homeostatic processes and play a critical role in empathy.

Furthermore, the neural overlap between the first-hand experience of pain and its third-person perception or

imagination is consistent with neural reuse theories which posit that neural circuits continue to acquire new use after an initial or original function is established (Anderson, 2010).

Altogether, results from these studies have bolstered the theory that shared representations between self and others rely on similar neural computations between first-person experience and third-person observation (Decety and Sommerville, 2003). Whether this overlap in activation between self and others reflects an identical neural population or originates from the intersection of adjacent and partially distinct activations is far from being established (see Box 1). One of the few studies specifically designed to address the extent of the overlap between felt pain and seen pain in others did not find identical activation in the anterior cingulate cortex, and thus did not support a mirrorlike interpretation (Morrison and Downing, 2007). Rather, the findings are more in line with general neural mechanisms involved in aversion-related processing, in which the ACC and anterior insula play a critical role.

Aspects of Empathy Specific to Humans

Humans have the capacity to feel empathic concern in response to a wide range of contexts in which others are in need, and even routinely extend this concern beyond conspecifics and onto other species. The development of human empathy has been elaborated through the integration of other abstract and domain-general high-level cognitive abilities such as executive functions, language, and theory of mind, underpinned by the prefrontal cortex (PFC), which expand the range of situations that can elicit empathy and the range of behaviors that can be driven by empathy (Stone, 2006).

Human language is a powerful tool to create and share emotional states, both by its content and prosody, which is not found in other species. By its very nature, language acts at a distance across space and, in the case of written language, across time (Harris, 2000). Conversation helps to develop empathy, for it is often here that people learn of shared experiences and feelings. Several empirical studies have now demonstrated that affective language dampens amygdala response (Lieberman et al., 2007) and facilitates exposure-related attenuation of autonomic reactivity to aversive stimuli (Tabibnia et al., 2008). Thus, the ability to communicate emotional states with others through speech and linguistic expression provides humans with a powerful means to share their emotional states with others and to extend the reach of empathic concern across space and time. Importantly, language production and comprehension are grounded in internal bodily states, and seem to involve circuits long associated with motor control functions (Pulvermuller, 2005), suggesting a rerepresentation of function and not the evolution of entirely new neurobiological processes.

Another seemingly unique aspect of empathy in humans is perspective taking, the cognitive ability to explicitly put oneself into someone else's shoes to represent his or her knowledge or emotional experience as compared with one's knowledge or affective experience. Such a capacity requires additional computational mechanisms (working memory and inhibitory control to hold simultaneously two perspectives in mind) needed for its development, which plays a critical role in promoting empathic concern. Neuroimaging studies have revealed a specific network of brain regions that are recruited when one takes the perspective of another individual to represent their knowledge or emotional experience as compared with one's own. Adopting a third person perspective, as opposed to a first person perspective has been associated with neural activation in the posterior superior temporal sulcus (pSTS) and medial prefrontal cortex (medial PFC) (Jenkins and Mitchell, 2011; Ruby and Decety, 2003, 2004). Studies in social psychology have demonstrated that empathic concern is enhanced when participants are told of another individual's plight and asked to imagine how that person feels (Batson et al., 1997). However, when the same individuals were asked to imagine instead how they would feel in the place of the other person, feelings of anxiety and personal distress were evoked. These results suggest that perspective taking helps keep feelings of personal distress at a distance, thereby permitting the emergence of empathic concern. To test this hypothesis, a functional magnetic resonance imaging (fMRI) study was performed in which participants viewed videoclips of individuals exhibiting facial expressions of pain, purportedly the result of a painful medical treatment (Lamm et al., 2007). Participants were instructed to either imagine how they would themselves feel if they were in the patient's

Box 1 The contribution of multisensory processing to the experience of empathy

Sparked by the discovery of sensorimotor neurons (AKA mirror neurons) in the monkey premotor and posterior parietal cortices that discharge both when a particular action is performed (such as grasping) and when the monkey observes the same action performed by another individual, a number of functional neuroimaging studies have documented that shared brain circuits are involved when processing one's own somatosensory and affective experiences and when one perceives these states in other individuals. For instance, participants scanned while watching video clips of a leg being touched or having their own leg being touched activates the secondary somatosensory cortex (Keysers et al., 2004). In another study, subjects observed a hand either being touched or not touched by a brush presented from either egocentric or allocentric perspectives (Schaefer et al., 2009). While both perspectives of viewing touch were associated with activation of the somatosensory, they also showed differences. The egocentric perspective yielded activation of the anterior part of SI and the allocentric perspective in the posterior part of SI. In addition, only the former perspective induced self-attribution of being touched oneself. The response in regions of the interoceptive sensory system, such as the posterior insula, processing the internal affective feeling states, is specifically modulated by the visual perception of other individuals' social or affective cutaneous experiences (Ebish et al., 2011).

Together, these data support models of embodied simulation proposing that multimodal cortical areas underlying first-person bodily experiences are also involved with an implicit, bottom-up understanding of the actions and emotions of other individuals, thus playing a role in intersubjectivity and empathic experiences (Decety and Grèzes, 2006; Gallese, 2003). Several authors have interpreted these studies as self-other overlap. At the neural level, the perception of another affective state activates neural regions or circuits in the observer that are also activated when he/she experiences the same affective state.

situation, or imagine what the patient was feeling. The former perspective was associated with a strong hemodynamic increase in the amygdala, AIC, and anterior cingulate cortex (ACC), as well as reports of anxiety and personal distress. When the participants were imagining what the patients were feeling, a significant reduction in activity was detected in the amygdala, with reduced feelings of anxiety combined with increased reports of empathic concern.

As illustrated by the example above, the evolutionary development of more complex neural systems, such as the regions of the medial PFC involved in perspective taking, has thus conferred greater behavioral flexibility and contextual control. For instance, Lamm et al. (2010) used fMRI to examine how participants empathize with the feelings of patients who reacted with no pain to surgical procedures but with pain to a soft touch. Results showed that empathizing with someone whose bodily and affective representations are distinct from our own recruited areas of the PFC involved in self-other distinction (medial PFC) and cognitive control (right inferior frontal gyrus), and these regions increased their functional connectivity with more phylogenetically older regions such as the amygdala, brainstem, insula, and PAG, that serve basic protective functions, including affective arousal.

Cognitive, sensorimotor, and somatovisceral mechanisms are thus intimately connected, and in line with neural reuse theories (Anderson, 2010) share similar computational resources. One salient example comes from work on humans that are experimentally induced to feel they have been ostracized. As expected, rejected participants reported and increase in negative emotions. However, when the identical study was done in an MRI scanner something far more interesting was detected. The act of being rejected actually brought about an increase in the activity of brain structures known to mediate the physiological response to pain (Eisenberger, 2011; Kross et al., 2011). Just as pain is a response to remove the organisms away from a noxious stimulus, the aversive feelings associated with social rejection represent a personal alarm alerting one that their status within the group may be compromised and motivates the individual to rebuild and reconnect social relationships (Cacioppo and Patrick, 2009). In this way, evolutionary processes are able to exploit an already online system that is fully capable of detecting and avoiding threats. Accordingly, knowledge regarding primitive neurobehavioral processes (e.g., pain, thirst) can provide important insights into higher level processes such as empathy that operate through an elaboration of these evolutionarily ancient and highly effective survival mechanisms.

Empathy as an Adaptive Response

Empathy is a flexible phenomenon, and its induction and expression are dependent upon various social and contextual factors. Clearly, it would be maladaptive to respond with care and to extend one's empathic concern to all. As noted above, rodents do not react indiscriminately to other conspecifics in distress (Langford et al., 2010). Recent neuroimaging studies in humans reveal that the neural network implicated in empathy for pain is modulated by various social and contextual factors. For instance, one fMRI study demonstrated that empathic arousal is moderated early in information processing by a priori attitudes toward conspecifics (Decety et al., 2009). Study participants were significantly more sensitive to the pain of individuals who had contracted AIDS as a result of a blood transfusion as compared with individuals who had contracted AIDS as a result of their illicit drug addiction (sharing needles), as evidenced by higher pain and empathy ratings and greater hemodynamic activity in areas associated with pain processing (i.e., AIC, aMCC, PAG). Furthermore, activity in the pain matrix network is enhanced when people viewed their loved ones in pain compared with strangers (Cheng et al., 2010). Another neuroimaging study demonstrated that the failures of an in-group member are painful, whereas those of a rival out-group member gives pleasure – a feeling that may motivate harming rivals (Cikara et al., 2011).

Empathic arousal is also modulated by an individual's knowledge and experience with pain. Two neuroimaging studies directly investigated how physicians react to the perception of others' pain. One study compared the neuro-hemodynamic response in a group of physicians and a group of matched control participants while they viewed videoclips depicting mild bodily harm (i.e., needle pricks) or being touched by a cotton swab (nonpainful situations) (Cheng et al., 2007). The results demonstrated activation of the pain matrix in the controls when they attended to the painful situations relative to the nonpainful ones. A different pattern of signal change was detected in the physicians; cortical regions underlying executive functions and executive attention were found to be activated, and unlike in the control group, no signal increase was detected in the pain matrix. A second study recorded event-related potentials (ERPs) from physicians and matched controls as they were presented with the same visual stimuli (Decety et al., 2010). The results showed early N110 differentiation between pain and no pain, reflecting negative arousal, over the frontal cortex, as well as late P300 over the centroparietal regions in control participants. In contrast, no such early ERP response was detected in the physicians.

Consequences of Being Empathetic

As empathy has evolved in the context of parental care and social bounds, it comes as no surprise that clinical empathy is an essential element of quality care. This interpersonal skill is an acknowledged essential component of professional competence (Epstein and Hundert, 2002). Patients desire it, and physicians who are empathic are more satisfied and have less burnout (Larson and Yao, 2005). There is evidence that perceived empathy is associated with improved patient satisfaction, adherence to treatment, as well as fewer malpractice complaints (Gleichgerrcht, & Decety, 2012). In contrast to models of 'detached concern,' physicians who attempt to understand what their patient is feeling and communicate their concern achieve a number of valuable outcomes for their patients and themselves (Halpern, 2012). Physicians' own emotions may help them attune to and empathically understand patients' emotional states, which may help produce a positive therapeutic impact. Sincere empathy is recognized as a major constituent in the practice

styles of excellent 'healing' clinicians (Schattner, 2012). Research shows that physicians' empathy actually improves patient outcomes for chronic diseases such as diabetes. One study including 891 patients with diabetes whose doctors had high empathy scores were better able to regulate blood glucose levels than patients whose doctors had low empathy scores (Hojat et al., 2011). Clinician empathy, as perceived by patients with the common cold, significantly predicts subsequent duration and severity of illness and is associated with immune system changes (Rakel et al., 2009). Doctors who show empathy have less malpractice complaints and better patient satisfaction and compliance (Huntington and Kuhn, 2003). Therefore, physician empathy can improve the patient's psychological and physiological adjustment to disease; a fact that should be earmarked for better communication throughout medical school training.

Conclusions

Even the most advanced forms of empathy in humans are built on more basic forms and remain connected to core mechanisms associated with affective communication, social attachment, and parental care. Empathy is not an all-or-none phenomenon, nor is it automatic or reflexive, as many social, interpersonal and contextual factors affect its induction and expression. The incoming sensory information is constrained and filtered by appraisal and reappraisal processing, which shapes the emergence of the experience of empathy and behavioral outcomes. As discussed above, empathy-related behaviors have coopted more primitive homeostatic processes involved in reward and pain systems in order to facilitate various social attachment processes. This evolutionary perspective is compatible with the nested brain-mind hierarchies view developed by Panksepp (2011), which posits that similar to other mammalian species, human emotions may spread across conspecifics, and at times these shared emotions may facilitate empathic concern, which promotes prosocial behaviors and altruism. Primary emotional processes, where sources of empathy may arise (i.e., feeling what other organisms are feeling), coordinate with secondary-process learning and memory mechanisms (i.e., knowing what others are feeling). Both of these then interact with higher mental processes, which can exert a variety of top-down influences on the regulation of empathic tendencies (i.e., desires to respond compassionately to others' distress). Once the capacity for empathy evolved, it came to be expressed outside the parental care context (de Waal, 2008). For instance, when people send money to distant earthquake victims in Haiti, or petition to support a bill that would contribute to curb the violence in Darfur, empathy reaches beyond its evolutionary origins, extending beyond inclusive fitness among kin and social group members. Along with enculturation, the development of empathy and caring is then further assisted by domain-general and high-level cognitive abilities such as executive functions, theory of mind, rational cognition, and language, which combine to expand the range and the scope of empathically driven behavior. Furthermore, the development of human empathy across history may have been facilitated by advancements and innovations from our past. Notably, Singer (1986) argued that over the course of history, people have enlarged the range of beings whose interests they value as value of their own.

Overall, the evolutionary conceptual view of empathy that we have developed in this article is compatible with the hypothesis that advanced levels of social cognition have arisen as an emergent property of complex interactions between the neurobiological structures underlying executive functioning and affect. Importantly, these cognitive functions are likely to rely and interact with preexisting neural circuits already possessing suitable resources. Similar neurobiological mechanisms that regulate parental behavior, attachment, and affective processing in all mammals interact with more recent cortical systems shaped by social, cultural, and educational contexts to produce the flexible and generalized forms of nurturant care found among humans. These evolutionary newer developments help explain why humans care not only for their offspring but also for strangers, and why they are motivated to uphold moral principles such as justice and fairness (Batson, 2011).

Abstract

In this article, we will highlight what is currently the most accepted definition of empathy, as well as definitions of similar aspects that are relevant for our understanding of empathy but which are conceptually different. This will be followed by a discussion of the underlying mechanisms of affect sharing, the specific component of empathy. In the last sections, we will present what we know about empathy development during the very first 2 years of life across cultures.

Our abilities to cooperate and understand others are most likely key to our success as a species. Among these, the ability to empathize with others is quintessential. Empathy is a multifaceted and complex psychological construct encompassing many subprocesses that have different developmental trajectories. During development, these components become progressively integrated, and some of the incipient forms are likely to disappear and not be observable at later ages. Hence, investigating and understanding early empathy development are invaluable. Looking at the very beginnings of empathy allows us to understand how the components of a system interact in ways that are not possible in adulthood, when the components are fully mature and functional (de Haan and Gunnar, 2009). Understanding how this ability develops is highly relevant for promoting adaptive social development and for an early diagnosis and intervention in the case of those pathologies characterized by atypical manifestations of empathy, like autism and psychopathy.

Defining Empathy and Related Concepts

After a brief overview of the past decade of literature on empathy (development or otherwise), one quickly becomes puzzled by the multitude of related but somewhat different concepts: empathy, cognitive empathy, emotional empathy, personal distress, emotional contagion, sympathy, compassion, altruism, prosociality, helping, and cooperation, to mention just a few. This multitude of concepts reflects scientists' attempts to differentiate between many aspects of a complex phenomenon. While this differentiation is useful for unrevealing such complexity and guiding research into the human ability to respond empathically to others and behave prosocially, clear definitions are necessary in order to avoid interchangeable use of the concepts and conceptual ambiguity, as well as an adequate approach into identifying the underlying mechanisms. The rise of social cognitive (and affective) neuroscience has been particularly responsible for such a movement toward formulating narrower definitions of empathy and related concepts, mostly due to its aims of establishing clear psychological and functional inferences about underlying processes of social behavior (Ochsner, 2007).

Recently, there seems to be a consensus toward defining empathy primarily as an emotional response (De Vignemont and Singer, 2006) triggered by observing or imagining another individual's affective state. Unlike other emotions, empathic responses are isomorphic with observed ones, and it appears as if we 'share' the affect we see in others, an experience that others have referred to as 'feeling with' the other. The isomorphism in empathic responses mostly refers to its valence, implying also that we can empathize with both the plight and the joy of another (Light et al., 2009). 'Feeling with' the other requires some level of awareness of the difference between our own emotions and those observed in another (Eisenberg, 2000). Depending on the intensity of the response, empathy can further lead to sympathy and motivate prosocial behavior or to personal or empathetic distress (Eisenberg and Eggum, 2009; Zahn-Waxler and Van Hulle, 2012). When not sufficiently regulated, these feelings with the other can be too intense and distressing for the observer, leading to withdrawal and a focus on the self rather than the other and hence being a potential precursor for nonadaptive and pathological responses (Zahn-Waxler and Van Hulle, 2012). Sometimes, in the literature the term 'empathy' is further divided into emotional and cognitive empathy. Emotional empathy refers mainly to the affective component, our ability to feel what others are feeling, while cognitive empathy refers to our ability to attribute mental states to others. As we will see Section Mechanisms of Affect Sharing, attributing mental states to others can be an important process involved in generating empathic emotional responses. However, it has different neural underpinnings from those functionally associated with affect sharing (De Vignemont and Singer, 2006), and it can be present outside the context of empathy response. We can, for example, try to understand what our friend is feeling without experiencing any emotion ourselves. Emotional contagion is another concept that is sometimes used to refer to empathy. It refers to the tendency to automatically mimic and synchronize facial expressions, vocalizations, postures, and movements with those of another person (Hatfield et al., 1994). Like the ability to attribute mental states, emotional contagion is an important process that could be involved in generating empathic responses (De Vignemont and Singer, 2006) but could also operate independently of such a context. For example, we can automatically mimic the emotional expressions of a person we interact with as a means of acknowledging that we have understood his or her emotions but without necessarily feeling the affect whose expression we mirror (Hess and Blairy, 2001).

When efficiently regulated, negative empathic responses can lead to feelings of concern or sympathy for the well-being

of the other, which represent a significant motivator for adaptive prosocial behaviors like helping and altruistic compassion (Knafo et al., 2008). Sympathy has always a negative valence, but does not need to be isomorphic with the observed emotion. A friends' sadness over the loss of a significant other may not lead to sadness in us, but to a great concern for this friend's well-being and a desire to see them well. At the brain level, it seems that sympathy is associated with the activation of the septal area, a brain area that has been functionally linked to the motivation for action (Morelli et al., 2012). Septal area is associated with individuals' prosocial behavior in their natural environment during daily life, and is activated when observing people experiencing various emotions like pain, anxiety, and happiness. Given this motivational value for behaving in the benefit of another, sympathy is also referred to as 'feeling for' the other.

While empathy, sympathy, and empathic distress are all emotional responses, prosocial behaviors like cooperating, sharing, helping, and comforting are acts that can sometimes rely on the motivational value of these emotions, but not always. For example, some forms of prosocial behavior could be the result of respecting preestablished social norms or of the joy associated with performing interesting activities in a social context. Also, some prosocial behaviors can be more altruistic in nature, while others are more instrumental, but most altruistic behaviors have as an ultimate goal the well-being of the other, with no evident benefit for the self and at least some cost to the actor, and in the absence of any external reward (Svetlova et al., 2007).

Mechanisms of Affect Sharing

Usually, three main groups of processes are involved in generating empathic responses: those related to the elicitation of affect sharing, emotion regulation, and self–other awareness. Undoubtedly, affect sharing is the component that is specific for empathy, the one that gives its unique characteristics among other emotional responses.

One of the major questions in empathy research concerns the mechanisms underlying our ability to 'catch' others' emotions. How can we feel what someone else feels when he or she experiences emotions such as sadness or happiness, or bodily sensations such as pain, in the absence of any emotional or sensory stimulation to our own body? Probably the most influential proposal is the perception–action model formulated by Preston and de Waal (2002). According to this model, when the observer attends to another person's emotional states, the observer's representations of similar states are automatically activated together with the associated autonomic and somatic responses, allowing him or her to experience the same emotion. This theoretical model has received some support from neuroimaging studies of empathy for pain, showing that part of the neural networks involved in firsthand experiences of pain are also activated when we simply observe someone in pain (Singer et al., 2004), and also from studies showing activation within the mirror neural system when observing emotions like sadness and happiness (Perry et al., 2012; Rameson and Lieberman, 2009). First discovered in the macaque premotor cortex, mirror neurons are a specific type of neurons that fire both when a monkey performs a hand action itself and when it merely observes another monkey or a human performing the same hand action (Rizzolatti et al., 1996), and it has been suggested that this is the main mechanism involved in imitative behavior. In humans, the same neural network involved in execution of an action (the supplementary motor area (SMA), pre-SMA, premotor cortex, supramarginal gyrus, intraparietal sulcus, and superior parietal lobe) is also activated when merely observing someone else performing the same action (Grezes and Decety, 2001). For what concerns affect sharing, it has been proposed that mirroring mechanisms are automatically activated when we observe others emoting. Both phenomenological observations and empirical evidence suggest that this is not always the case. We do not empathize with everyone we see or think of, and not always. This can actually have an adaptive value. If, for example, others' emotional signals are confusing, it would be not efficient for us to empathize with such an ambiguous state.

Appraisal of other contextual information like the personality characteristics of the observed person (e.g., fairness) or their group affiliation (e.g., in- vs out-group) has been shown to modulate the activation of the neural network involved in empathy for pain (Lamm et al., 2011; Singer and Steinbeis, 2009) and speak against a fully automatic bottom-up driven empathy. Although mimicry mechanisms could be involved in generating affect-sharing responses, for some type of stimuli the affect programs could be triggered by the perception of emotional stimuli independent of conscious visual recognition and even when the emotion is communicated via other motor means than those through which it is reproduced. Tamietto and De Gelder (2008) have shown that when adults are presented very briefly with bodily expressions of fear, their facial muscles specific for expressing fear become activated as in expressing the emotion, even though they have not seen the actual facial expression. This speaks against a perception–action mechanism, as the observer reproduces an expression that has not been perceived. It could thus be that for some emotional stimuli like those signaling danger, affect sharing is the result of triggering affect programs by the mere perception of the emotional stimuli.

There are situations in which the observable cues about the emotions that others experience are missing, either because we are not in direct contact with them or because these cues are ambiguous. In these instances, top–down processes like inferences about mental states (both cognitive and emotional) are involved in generating affect-sharing responses. Rameson and Lieberman (2009) have asked adults to observe people displaying various emotions and also to try to empathize with them while their brain activity was recorded. Participants' subjective reports of felt empathy were associated with increased activation in the brain areas involved in inferring the mental states of others (the medial prefrontal cortex and precuneus) and recognizing emotional expressions (the ventrolateral prefrontal cortex) alongside parietal mirror regions. This activity was particularly stronger when participants made an effort to empathize with the observed others, and also when certain emotions were more ambiguous (e.g., anxiety or sadness) and required reference to contextual cues.

Development of Empathy in the First Years of Life

Although the literature documenting the development of empathy in the first 2 years of life is scarce and many questions regarding the underlying mechanisms are yet to be answered, most current evidence converges to suggest that the ability to respond empathically to others' emotions is present very soon after birth.

Negative Empathy

When being exposed to vocal expressions of distress, like the cry of another infant, 18- to 72-hour-old newborns manifest facial and vocal negative emotions themselves, associated with increases in arousal as indexed by heart rate (Sagi and Hoffman, 1976; Simner, 1971). Given that initially newborns were found to cry whenever hearing another infant crying, these reactions have been suggested to indicate automatic and undifferentiated emotional contagion, akin to emotional mimicry, rather than regulated empathic responses associated with some awareness of self as different from the perceived other. This interpretation was supported by the view that newborns and young infants are not proficient in regulating their emotions, and do not have an explicit representation of self. However, we now know that from birth, infants have at least some incipient abilities to regulate the arousal they experience. They also have an implicit sense of self based on multisensory integration of information about their own body (Rochat and Striano, 2001). These abilities are highly relevant for infants' empathic responses, and the existent evidence suggests that they are already involved to some extent in generating affect-sharing responses in newborns. For example, newborns do not cry or manifest facial distress so intensely when exposed to their own prerecorded cry or when presented with the cry of a newborn from a different species (i.e., a newborn chimpanzee), suggesting that these negative affect-sharing responses are empathic in nature (although more empathic distress) rather than undifferentiated emotional contagion.

Later, during the first year of life, similar empathic responses persist, with 2-week- to 24-month-old infants manifesting negative emotional responses to another in distress (Field et al., 2005; Geangu et al., 2010; Nichols et al., 2009; Roth-Hanania et al., 2011). The cues to others' emotions that can elicit such responses are varied, including auditory (most often, a cry sound), visual (facial and bodily expressions of distress), and contextual. These affect-sharing responses are associated with stable levels of implicit self–other awareness, and infants engage age-specific strategies for regulating these empathic responses (Geangu et al., 2011a). For example, while younger 3-month-old infants use more rudimentary behaviors known to have a regulatory function, like thumb sucking, in order to delay or reduce in intensity their responses, older 6-month-old infants use more advanced attentional strategies known to become increasingly efficient at this age. Infants' success in regulating these affect-sharing responses to an adaptive level, and hence to manifest negative empathy rather than empathic distress, seems to be dependent on the intensity and the duration of the emotional cues they are exposed to (Roth-Hanania et al., 2011). Although no systematic investigation has tested this proposition, existent empirical data suggest that infants' attempts to regulate even the more intense emotions they observe in others are successful depending on their duration. For example, 3- to 9-month-old infants start crying only after they have heard another infant crying for approximately 2–3 min (Geangu et al., 2011a).

At the age of 9 months, infants' ability to discriminate between their own body and that of a peer is associated with a reduced empathic distress toward another infant's cry (Geangu et al., 2011a). This bodily self-awareness is based on an implicit intermodal body schema that integrates information related to bodily space, intermodal timing, and intermodal forms of action (Rochat and Striano, 2001), and probably allows infants to distinguish between experiences that are genuine to their own body and those of others. Toward the age of 9 months, infants become better able to differentiate between self and others more than in terms of bodily sensations. They begin to understand that others have different intentions from their own, intentions that motivate their behaviors (Tomasello, 1995).

Infants' increasing abilities to experience varied emotions are probably also relevant to their diversity of responses to others' emotions. For example, sadness is an emotion that is usually displayed later in the first year of life, and this disposition is related to how much infants respond with sad facial expressions to the cues of a peer in distress (Geangu et al., 2011a).

Positive Empathy

Infants are able to resonate not only to others' negative emotions but also to their positive ones. Although evidence in this respect is limited, it is highly informative. Young 2-month-old infants respond with matched facial expressions of happiness when their mothers display vocal and facial expressions of positive emotions (Haviland and Lelwica, 1987). Similar patterns of results have been recorded in 4- to 6-month-old and 7- to 9-month-old infants, who responded with positive behaviors to a happy female face and with negative behaviors to an angry face (Serrano et al., 1995). While these emotional expressions may represent just the use of adequate social interaction means, they may also indicate empathic-like responses. When the cues for social interaction were reduced, Geangu et al. (2011b) found that both 6- and 12-month-old infants show an increased emotional arousal, as indexed by increased pupil dilation, for another's joy but for shorter duration than for perceived distress. The increase in arousal to positive emotions compared to neutral states has a longer delay for 6- than for 12-month-old infants. When such differentiation occurs, it follows a pattern specific for a negativity bias, with increased arousal for negative compared to positive emotions. This is similar to adult brain activation during empathy for positive and negative emotions. While similar networks are activated in both cases, during negative empathy their level of activation is higher (Perry et al., 2012).

The mechanisms underlying infants' abilities to share others' positive and negative emotions and ultimately feel empathy toward them are still issues of debate. Until recently, the most influential hypothesis was the one formulated by Andrew Meltzoff (2002) which relied heavily on the principles of

simulation theories. It assumes that infant empathic responses have their origins in infants' innate abilities to imitate, to map the actions of other people onto actions of their own body. Most of the supporting evidence comes from studies suggesting that newborns can imitate simple orofacial acts like mouth opening, pouting, and tongue protrusion, as well as some manual acts like index finger extension and sequential finger movements (Jones, 2009). However, empirical evidence has emerged to suggest that alternative mechanisms like exploration-associated arousal could explain such effects, while the same effects observed in newborns have not been replicated with older infants (Jones, 2009; Ray and Heyes, 2011). Evidence is even less compelling regarding newborns' and infants' abilities to mimic emotional facial expressions, which raises serious doubts that the affect-sharing responses we observe in infants are actually mediated by emotional mimicry mechanisms. Obviously, more investigation is needed before drawing conclusions regarding the mechanisms of affect sharing, at least for the first year of life. At the moment, it seems that alternative views, including those referring to subcortical routes of emotional processing (probably specific for negative emotions), are equally plausible (De Gelder et al., 2004).

Sympathy

Although both infants and adults seem to respond empathically stronger to negative rather than to positive emotions, the fact that infants are able to empathize with others' joy is of particular interest. Older children who empathize with another's joy are more likely to show an increased frontopolar activation known to be engaged in experiencing positive emotions (Light et al., 2009).

It has been suggested that this increased frontopolar activity enables children to integrate information about their own emotional states with the information about other's emotional states (Light et al., 2009). It may be thus possible that the empathic happiness we record in older infants could index, among other things, more engagement of the frontal areas of the brain. As suggested in this article, frontal areas of the brain are recruited in many social cognitive processes. At the behavioral level, we do have evidence that older infants and toddlers do engage more in trying to understand the situation that led to another's distress and their emotions (Roth-Hanania et al., 2011), and that this ability, and not the affect sharing per se, keeps developing beyond infancy and toddlerhood (Knafo et al., 2008). Infants and toddlers' abilities to engage social cognitive processes in understanding another's plight are strongly related to their ability to manifest sympathetic concern and with the emergence of their other-oriented prosocial behavior (Nichols et al., 2009; Roth-Hanania et al., 2011). Already at the age of 8 months, infants manifest clear, although moderate, signs of sympathetic concern for another's distress. These gradually increase toward the age of 20 months and characterize children's responses across various situations, involving both family members and strangers (Knafo et al., 2008; Roth-Hanania et al., 2011). Importantly, children who tend to manifest sympathetic concern at an early age show this tendency consistent across the following years (Knafo et al., 2008). Although sympathetic concern is present to a certain degree very early (at the age of 8 months), it seems to become an important motivator for prosocial behaviors only beginning with the second year of life; this is probably dependent on the development by children of a repertoire of adequate behaviors and their ability to functionally link these with the needs and desires of their recipient (Brownell et al., 2009). It is at first more prominent for a child's familiar environment, as children seem to more readily help their mother than a stranger. But, by their third birthday, sympathetic concern motivates prosocial behavior in more varied contexts, including those involving strangers (Knafo et al., 2008).

Cross-Cultural Aspects of Empathy Development

Although children's tendencies to manifest sympathetic concern during their first 3 years of life are to a large extent due to inherited factors, the social environment is equally important and seems to shape the expression of such genetic components (Knafo et al., 2008). That empathy becomes in adulthood strongly linked to social context has received strong support from both behavioral and neuroimaging studies that showed, for example, that adults who watch someone in pain will manifest more empathy if the person they see is a member of their own group rather than one belonging to an adverse one (Hein et al., 2010).

The development of many of the underlying mechanisms of empathy and prosocial behaviors has been shown to be sensitive to the cultural environment in which children live. Parents and siblings are important socialization agents at earlier ages. It is thus expected that the final product, the complex empathic response, will also be shaped by culture.

Infants' abilities to express and regulate emotions develop on different trajectories depending on the culture in which they grow up. When exposed to frustrating or painful situations, young infants from East Asian cultures like Japan manifest longer latencies to the first signs of distress and are more quickly soothed than the North American ones (Camras, 1992), even though they manifest higher arousal (Camras et al., 1998). Such differences in the early development of the ability to express emotions can be even observed within the same macro-cultural environment. For example, Chinese infants manifest less facial motility specific to emotional expressions in response to frustrating events than Japanese infants.

The way in which parents interact with their own children, including their socialization practices, is shaped by the traditions and norms of the culture in which they live. For example, the mothers in the Nso tribes in Cameroon carry their infants closely tied to their bodies and do not engage much in face-to-face interaction or encourage them to explore the objects in their close environment. This seems to be related to a relatively delayed development in children's explicit representations of self as indexed by the mirror self-recognition test when compared to children from Western countries (Keller et al., 2004). Empathic emotional responses are, by definition, associated with a minimal awareness of the difference between our own emotions and bodily sensations and those observed in another. Yet we do not know to which extent

this close bodily contact influences the development of all levels of body awareness beyond explicit representations and whether they have an impact on their ability to express empathic responses. If this is indeed the case, could it be that Nso infants are more prone to less self–other differentiated affect sharing and empathy? Societies like Cameroonian Nso tribes have communal social structures in which people live in close bodily proximity. In this case, higher tendencies to respond with a low level of self–other differentiated affect sharing may increase the sensitivity to many others' emotional cues and help build multiple attachment bonds (Kärtner et al., 2010; Keller, 2012).

Empirical Legal Studies

Christopher Zorn, Pennsylvania State University, University Park, PA, USA

Abstract

Empirical legal studies (ELS) is a burgeoning field of scholarly inquiry situated at the intersection of law and the social sciences. The contemporary ELS movement began in the 1990s, and was primarily the result of an interdisciplinary group of scholars working in U.S. law schools. ELS is broadly characterized by a commitment to a positivist epistemology, an emphasis on quantitative methods of inquiry, and a substantive focus on matters of legal policy. By the first decade of the twenty-first century, ELS had created a professional association, an annual meeting, a quarterly peer-reviewed journal, and a widely viewed weblog.

Introduction

It is tempting to begin any discussion of empirical legal studies (ELS) with Justice Holmes' famous line from *The Common Law*, where he notes that "(T)he life of the law has not been logic: it has been experience." Holmes' quote claims both too little and too much. On the one hand, the law is clearly much more than its operation. At the same time – as any good historian knows – not all experiences contribute equally to the evolution of society; the 'experience' that mattered to Holmes in *The Common Law* was not comprehensive, and was in fact a different (and substantially more attenuated) version than that deemed influential by contemporary scholars.

In a similar fashion, 'ELS' is both broader and narrower than one first encountering the term is likely to realize. For those steeped in one of the traditional social sciences, it is easy to think of ELS in the confines of one's own discipline; upon seeing the broader, interdisciplinary picture of the subject, one is often struck by the scope and diversity of social scientific work on legal phenomena. In the early twenty-first-century United States, however, the term 'ELS' also comprises a well-defined movement in the legal and social scientific academy. While the sense of ELS as a movement is the central focus of this article, I hope also to make clear how the movement relates to the broader meaning of the term.

Origins

In its contemporary sense, ELS refers most directly to a professional association (the Society for Empirical Legal Studies, or SELS), the primary activities of which are to publish a peer-reviewed journal (the *Journal of Empirical Legal Studies*, or *JELS*) and to host an annual conference (the Conference on Empirical Legal Studies, or CELS). ELS was not the first coordinated effort on the part of a group of scholars to address questions of the law empirically. It was preceded most recently by the law and society movement of the 1960s and 1970s (as constituted, inter alia, by the Law and Society Association (LSA), the *Law and Society Review* (*LSR*), and the National Science Foundation's Law and Social Sciences program), by the law and economics movement begun in the 1950s, and – before that – by the legal realists of late nineteenth and early twentieth century. In challenging conventional approaches to the study of the law, and in demonstrating the value of empirical (rather than purely theoretical) analyses to that study, those influential enterprises laid the groundwork for ELS.

Existing accounts date the origins of the contemporary ELS movement to the decade of the 1990s. Suchman and Mertz, for example, note that "Harvard opened what may have been the nation's first self-proclaimed Program on Empirical Legal Studies" in 1996 (2010: 556–557), and Kritzer's review of more than a century of empirical work on the law dates the term's widespread use to "around 2000" (2009: 925). While the exact instant of the movement's origins probably cannot be known, what is clear is that, beginning in the last decade of the twentieth century, scholars in the social sciences and the legal academy who were investigating legal questions using empirical methods began to coalesce into a new organization.

The roots of this new movement were different in many respects from those of its predecessors. Whereas the institutionalization of law and economics was predominantly (and unsurprisingly) the task of economists, and the origins of law and society were largely the disciplines of sociology and criminology, ELS's founders were in a disciplinary sense more diverse, hailing from political science, psychology, economics, public policy, and a smattering of other fields. Chambliss notes that "(A)mong the eight founders of SELS, four have Ph.D.s: one in economics, one in psychology, one in education and social policy, and one in political science" (2008: 32–33). And as Eisenberg (2011) notes, in addition to their close disciplinary ties, both LSA and the American Law and Economics Association owe their origins at least in part to funding by external organizations: the former, to the Russell Sage and Walter E. Meyer Foundations, and the latter to the Olin Foundation. In contrast, SELS was founded without either a strong disciplinary affiliation or any external foundation support; instead, as Eisenberg (2011) details, it received initial support from law schools, especially Cornell. As a result, it lacked both the clear disciplinary and ideological orthodoxies of other similar associations.

At the same time, the ELS movement was also narrower than those organizations in other respects. It was, at least initially, almost entirely made up of faculty with appointments in elite law schools, rather than in the social and behavioral

 http://dx.doi.org/10.1016/B978-0-08-097086-8.86135-8

sciences. It was also almost exclusively positivist in its epistemological outlook, quantitative in its methodological approach, and policy-oriented in its substantive focus. In an influential early essay, Michael Heise (one of the founders of ELS) defined ELS as "the subset of empirical legal scholarship that uses statistical techniques and analyses" (Heise, 2002: 821). Similarly, the editor's introduction to the first issue of *JELS* noted that "The central purpose of *JELS* is to add to knowledge of the legal system based on observation or empirical analysis, including experimental analysis," and that "*JELS*'s editorial board is committed to providing expert statistical evaluation of manuscripts with the goal of raising the level of statistical sophistication in empirical legal scholarship." While this emphasis has changed somewhat over time, the predominant methodological tools adopted by ELS's adherents remain quantitative (primarily statistical studies of observational data, but also laboratory and field experiments), and the central topics addressed by research appearing at CELS and in *JELS* are of a policy nature, albeit those familiar to a legal audience.

As a professional association, ELS began with the creation of *JELS* at Cornell University Law School, under the editorship of Professors Theodore Eisenberg, Jeffrey Rachlinski, Stewart Schwab, and Martin Wells. The first issue of *JELS* was published in 2004. Shortly thereafter, a group of organizers hosted the first CELS at the University of Texas – Austin in October 2006. That conference drew more than 200 participants, and was followed by annual meetings at NYU (2007) and Cornell (2008). Subsequent CELS gatherings were hosted by USC, Yale, Northwestern, Stanford, the University of Pennsylvania, and UC–Berkeley. In February of that same year (2006), an affiliated group of scholars launched the Empirical Legal Studies Weblog. Soon after that initial conference, Eisenberg and seven others founded SELS, an umbrella organization responsible for the administration of *JELS* and CELS. SELS was registered in New York as a federal 501(c)(3) organization in 2011. SELS membership is open; annual membership dues include a subscription to *JELS*.

ELS Today

In the decade or so since its creation, SELS has grown considerably in size and influence. SELS currently has nearly 500 individual members; attendance at the 2013 CELS was 350. Unlike other similar meetings, presentation of research at CELS is refereed and selective; the acceptance rate for papers submitted to the 2012 CELS conference was 28%. *JELS* is published quarterly, and is available at 3480 academic and other institutions worldwide via license, and at another 5200 institutions in the developing world via philanthropic efforts. *JELS*'s 2013 impact factor (the average number of times articles from the journal published in 2011–12 were cited in 2013) was 1.067; Eisenberg's analysis of the Washington and Lee Law Library Database also shows that JELS ranks "in the top five" among social science journals indexed, and "in the top 5%" of all refereed journals considered (2011: 1725 and Table 2). Eisenberg (2011: Table 1) also demonstrates that, at least during the first decade of the twenty-first century, the disciplinary affiliation of *JELS* authors was more disciplinarily diverse than either that of authors in *Law and Society Review* or the *Journal of Legal Studies*, two long-running and prominent journals with their roots in the social sciences. Based on the data reported in Eisenberg's (2011) Table 1, the 2004–10 disciplinary Herfindahl index (a measure of the concentration of authors within disciplines) for JELS was 0.23; the corresponding statistics for *JLS* and *LSR* were 0.70 and 0.97, respectively.

The development of ELS over the past two decades has paralleled (and, to varying degrees, propelled) a more general empirical turn among legal scholars. In 2006, the Association of American Law Schools took as the organizing theme of its annual meeting 'Empirical Scholarship: What Should We Study, and How Should We Study It?' And as numerous scholars have noted, research with an empirical component is now commonplace in law reviews. In one recent example, the *Stanford Law Review* dedicated an issue to 'The Empirical Revolution in Law'; in their introduction to that issue, Ho and Kramer show that the incidence of articles using the word 'empirical' in that journal have risen from effectively none in the 1950s and 1960s to (on average) 60% of all research published there (Ho and Kramer, 2013: Figure 1).

On the pedagogical front, courses on empirical methods (primarily, but not exclusively, quantitative) are now a regular part of the curriculum at many law schools; a current (and very incomplete) list of major law schools offering such courses includes Chicago, Cornell, Harvard, Illinois, Northwestern, Stanford, UCLA, Vanderbilt, Washington University, and Yale. Law schools are also increasingly hiring faculty who hold both a JD and a PhD, and in some instances have made prominent appointments of empirical scholars with a social science PhD alone.

Disciplinary reactions to the rise of ELS – and of empirical work on the law more generally – have varied widely. Among conventional doctrinal legal scholars, responses have varied from enthusiasm through skepticism to outright disdain. The nature of the reactions track broadly with the degree of involvement with empirical work on the law; scholars focusing on areas of the law that are intrinsically amenable to empirical analysis (e.g., antitrust, election law, and so forth) have tended to be more receptive to such work than those working in less empirically relevant areas (such as legal philosophy).

Among the social sciences, disciplinary reactions also generally correlated with the degree of involvement in ELS by members of that discipline. On the one hand, scholars of legal phenomena in political science, economics, and psychology – those fields with substantial representation and involvement in the ELS community – generally welcomed the new organization. While ELS's impact on some other fields (notably anthropology) has been minimal, perhaps the strongest reaction has been among sociologists, particularly those associated with the 'law and society' tradition of sociolegal research. As early as 2006, scholars in those areas wondered aloud whether ELS "will become a more complacent, insular, and technocratic endeavor" than the law and society movement, and whether "the sociology of law, as we know it, may become even more marginal in the legal world than it is today" (Suchman, 2006: 3; see also Suchman and Mertz, 2010: 574–575). Chambliss characterized ELS as "a movement by a group of social-science-trained law professors … to build their

reputations and careers by creating a market demand – 'empirical legal studies' – and filling it" (2008: 31); this was possible because "scientism sells, especially when it is pitched by faculty from prestigious universities" (2008: 36). She recommends a policy of careful disengagement, where "epistemological, theoretical, and political debates" take place in other contexts, leaving ELS "to fight the common enemy of junk science and pseudo-research" (2008: 24).

These responses, both within and outside of the legal academy, are in many respects unsurprising. In addition to their conceptual distance from empirical work, doctrinal scholars in law schools are also the least likely to have the training critically to evaluate empirical work (or the inclination to seek it). In the social sciences, the absence of any substantial 'critical turn' in the fields of psychology, economics, or political science leaves little cause for epistemological disagreement with members of the ELS community. In contrast, sociologists of law and members of the law and society community have embraced that turn, and as a result are deeply – and sometimes irredeemably – skeptical about ELS's central tenets of positivism, quantification, and policy emphasis.

The Future of ELS

The institutionalization of ELS into the contemporary legal and social science academies is largely complete. In addition to the growth of SELS itself, empirical work on legal phenomena of the sort undertaken by ELS members constitutes large and in some cases dominant bodies of research on the law in economics, political science, psychology, and other fields. Empirical scholars are also increasingly integrated into legal education; conversely, legal academics with an empirical bent are finding an increasing willingness to collaborate on the part of scholars in the social sciences.

Research by members of the ELS community has also been notable for its impact. An early review by Eisenberg (2004) noted that ELS research received significant attention from mainstream media; for example, by the time of publication of its first issue, research findings appearing in *JELS* had been featured in the *New York Times*, the *Economist*, the *Financial Times*, the *Wall Street Journal*, and the *International Herald Tribune*. The movement has also had a visible impact in legal education. Beyond offering courses in empirical methods, ELS adherents have called for – and in some cases prompted – changes to the ways in which legal publications are edited (encouraging the adoption either of a system of peer review or of mandatory data disclosure and replication for empirical work appearing in student-edited law reviews).

The popular attention to and increasing emphasis of empirical work in law schools has in turn contributed to the growing use of quantitative data and analytics in the legal services industry, particularly among large U.S. law firms. It has also influenced the development of private-sector companies that provide analytical and empirical expertise to actors in the legal industry, including law firms, in-house legal departments, and law schools. While some of these changes undoubtedly reflect the larger move toward greater and more sophisticated use of data in business, their development in the notoriously slow-to-adapt legal services industry was arguably fostered by the visibility of quantitative, empirical research on legal issues, and on the increased exposure of young attorneys to such research during law school.

Beyond its intended impacts, ELS has also prompted developments in the larger field of social scientific work on law. One of these is the creation of what its adherents term 'New Legal Realism' (NLR), which has been variously characterized as a parallel movement (Eisenberg, 2011; Lempert, 2013), a counterpoint (Suchman and Mertz, 2010), or a competitor (Chambliss, 2008: 24) to ELS. To the extent that it possesses a coherent outlook, NLR exalts 'law in action,' 'bottom-up' approaches to the study of law, and interdisciplinarity. In part because of the hegemonic influence of the older sociological 'law and society' tradition upon it, NLR is also infused with a progressive political agenda that distinguishes it from ELS. No similar countermovements have yet been observed in economics, psychology, political science, or the other social sciences to which ELS bears a connection.

ELS itself has also evolved, at least partly in response to the issues raised by its critics. While the research presented at CELS and published in *JELS* is still predominantly positivist, quantitative, and policy-focused, its institutionalization has allowed the movement and its adherents to become broader and more self-reflective. The fraction of work employing qualitative and mixed methods that appears in *JELS* has increased somewhat since the journal's creation; while maintaining its disciplinary diversity, current issues also exhibit a wider range of methodological approaches. In recent years the movement's leaders have also welcomed critical reflection; for example, the aforementioned *Stanford Law Review* special issue is comprised of a series of essays by prominent non-ELS scholars responding to and critiquing bodies of work presented at the 2012 CELS.

At the same time, the central tenets of the movement remain fundamentally unchanged. The movement's greater acceptance of qualitative and historical methods is consistent with its continuing dedication to a positivist (rather than relativist/constructivist) epistemology. And the movement so far shows no particular inclination to try to "escape the pull of the policy audience" (Suchman and Mertz, 2010: 575). This is also somewhat unsurprising; as Chambliss (2008) notes, the intersection of ELS's three central characteristics – a commitment to a positivist epistemology, an emphasis on quantitative methods of inquiry, and a substantive focus on matters of legal policy – make it particularly well positioned to inform and contribute to policy making.

Going forward, a number of larger societal phenomena point to the continued viability and growth of ELS. In particular, the ever-increasing availability of digital data on socio-legal phenomena, the growing power of computers to visualize and analyze those data, and the rising prominence of legal academics in government and policy circles would all seem to be consistent with the ELS mandate. So too does the increasing demand for evidence-based and data-driven decision-making in the public and private sectors. Together with the increasing demand for empirical research in the legal academy, these trends augur the ongoing vibrancy of ELS as a scholarly endeavor.

Abstract

Empirical social research (ESR) uses empirical data on social formations and their members as a basis for explaining social phenomena. Historically it developed in three stages. The first stage was represented by the changes introduced into scientific procedure by the Chicago School of Sociology between 1895 and 1929. The second stage began outside the field of sociology in the late 1920s with the use of standardized data on social units (individuals and households) for marketing and polling purposes, and the approach was then applied in sociology starting in the later 1930s; most social data processing at this time were descriptive in nature and purpose. The third stage involved use of the same mass data in the survey analysis model of research to test hypotheses on causal relations between selected variables. The aim was to develop 'theory-based ESR.' ESR refers to empirical research activities grounded in social theory and enriching social theory.

For some decades now, empirical social research (ESR) has been contributing to knowledge through the collection and evaluation of social data and the testing and enriching social theories. Alongside the history of sociological thought and in parallel with the history of social theories we therefore need to study the history of ESR. This will help us to understand how important discoveries were made, and explain the methods by which significant theories were confirmed or challenged.

Definition

'ESR' must be distinguished from the related terms 'survey,' 'social survey,' 'survey research,' and 'survey analysis.' 'Survey' or 'survey research' is a general term for standardized mass questioning of a representative sample of individual members of a population under study. The 'history of the social survey movement' refers to the emergence and development of the use of survey techniques, primarily in the work of British charities in the nineteenth and early twentieth centuries, and then in similar activities in the United States in the first two or three decades of the twentieth century. This research work was conducted mainly in urban conditions, and was aimed at identifying and addressing negative social phenomena such as poverty, bad working conditions, suicide, discrimination, racial segregation, social exclusion, and crime. The concept of 'ESR' refers to survey activity that has clear scientific applications in either basic or applied research, but it also includes scientific activities carried out by social scientists with the same or similar objectives but not using the survey technique. *The history of ESR is thus the history of research activities that have used empirical data on social formations and their members to identify and then offer explanations for social phenomena relating to social groups, communities, social institutions, or social processes.* As we understand the term, ESR generally means 'theory-based ESR,' i.e., research grounded in social theory and yielding results that enrich social theory.

While it may include some activities that did not have social scientific applications, the 'history of survey research' is nevertheless largely a part of the 'history of ESR.' Indeed, the most valuable achievements of the social survey movement, which influenced the very nature of the emergent social sciences in the first decades of the twentieth century, form a very important part of the history of ESR. In the late 1930s and 1940s survey analysis was based on use of an abundant body of data and careful formulation of problems in an effort to discover causal explanations for the social phenomena studied, and as such it pushed ESR toward ever greater applicability in the construction or enrichment of sociological theory.

The Main Trajectories and Stages in the History of ESR

It is possible to distinguish three stages in the institutionalization of ESR. The first stage is most comprehensively represented by the series of changes introduced into scientific procedure by the Chicago School of Sociology between 1895 and 1929. Its new research model made the 'Chicago school' the most important center of scientific sociological research in the United States in its day. The second stage started with the widespread use of standardized data on social units that emerged outside the field of sociology in the late 1920s and came to be applied in sociology in the second half of the 1930s and later. Most of the data processing conducted at that time were of a descriptive nature, and so the third stage began when the same mass data that had been used earlier just for descriptive purposes were employed by the creators of the survey analysis model of research to test hypotheses about the causal relations between the variables studied. (cf. Arguments on the three stages of institutionalization of ESR in Jerabek (2012) and Converse (1987).)

The Origins of the Collection and Analysis of Social Data – Europe

In the period from the seventeenth to the nineteenth century the first steps were taken in the collection and analysis of data on society. The collection and use of such data were driven by two different purposes. One was administrative, and a matter of the increasing demands on the government. The other was statistical and a response to the practical needs of the emerging insurance industry and science; the aim was to predict and explain patterns of mass phenomena in society.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.03217-7

The next period, from the 1890s to the end of the World War II, is generally regarded as the time when ESR acquired firmer contours. During this period ESR became fully institutionally established, i.e., it gradually became a legitimate part of academic sociology. This process culminated in the late 1940s in the United States and subsequently in Europe and other parts of the world.

The Administrative Use of Empirical Social Data

The administrative use of empirical social data was connected with government, the drafting of legislation, and territorial administration. This line of activity was based on the work of William Petty, who in 1672 wrote a report on the economic and social structure of Ireland (*The Political Anatomy of Ireland*). The socioadministrative line then progressed in centralized France, where Jean-Baptiste Colbert, controller general of finances, and, after him Marquis de Vauban, collected data necessary for the administration of the country. This stage culminated in a survey describing 32 administrative districts of France, 'The Grande Enquete,' initiated in 1697 (Lecuyer and Oberschall, 1968, p. 38). The line was developed further in the eighteenth century in the work of the Encyclopedistes Jean S. Bailly, Antoine L. Lavoisier, and Pierre S. Laplace, when they reorganized the network of hospitals in France in the years 1785–89. Pierre J.G. Cabanis continued in this spirit in the next century as part of the 'hygiene movement' (Lecuyer and Oberschall, 1968, pp. 39–40). The reform movement in Great Britain from the end of the eighteenth to the middle of the nineteenth century was represented by John Howard (1777), Frederick Morton Eden (1797), J.P. Kay-Suttleworth (1832), and Edwin Chadwick (1842) (Lecuyer and Oberschall, 1968, pp. 40–41). A similar line of research was then supported by the British Parliament, which ordered numerous reports on poverty, the health of the population, child labor, working conditions in factories and so on. Martin Bulmer refers to this trend as *Blue Book Sociology* (Bulmer, 1985b: 6). The data obtained in the preparation of these reports between 1833 and 1897 were used as a basis for legislation in Great Britain. (One of the longest reports, the 'Report on Labor,' drawn up in 1893–97, is remarkable for the enormous amount of material it compiled; it drew on interviews with 583 witnesses, posed 97 336 questions, and distributed 5350 questionnaires, 2100 of which were returned completed (Zeisel, 1974, p. 103).)

Charles Booth is generally considered the most prominent representative of the administrative line of collection of empirical social data. From 1886 to 1897 he organized the collection of a large amount of empirical material as a basis for his study of poverty and the living conditions of London's working class (Bales, 1991). In the course of more than a decade he published the successive volumes of his series *Life and Labour of the People in London* (Booth, 1889, 1891, 1892–1897, 1902–1903). He made it his goal to provide an accurate map of the full scale of poverty in the population of London. Booth decided to undertake a laborious survey (conducted door-to-door, and in subsequent surveys street by street) (Bales, 1991, p. 97) in which he collected empirical data with the aid of a dense network of school inspectors, who were well acquainted with the workers' families (Bales, 1991, p. 74).

Booth was unquestionably a source of inspiration for many other researchers, especially in the United States. The latter carried out their own investigations, for which the term 'social survey' was introduced. Booth's immediate successor in Britain was Benjamin Seebohm Rowntree. In *Poverty. A Study in Town Life* he investigated the population of York and used his results as a basis for a distinction between primary and secondary poverty. Primary poverty meant living below a certain minimum income level, whereas secondary poverty involved the imprudent or uneconomical use of resources, with consequences that were often worse than the effects of primary poverty (Kent, 1985, pp. 52–61; Hennock, 1991, pp. 190–195).

The next studies of similar phenomena, initiated and conducted by Arthur L. Bowley (Bowley and Burnett-Hurst, 1915; Bowley and Hogg, 1925), used sampling procedures in data collection. In 1928, Llevellyn Smith published the *New Survey of London Life and Labour*. This was a replication of the studies done by Charles Booth in London, allowing historical comparison of the new findings with Booth's observations and at the same time a methodological comparison of Booth's exhaustive survey technique and Bowley's 'sampling' procedure (Kent, 1985, pp. 52–59).

The Statistical Use of Empirical Social Data

The purpose and goal of the second line of data collection, i.e., the statistical evaluation of collected empirical data, were to identify 'quantitative social laws' or at least patterns observed in figures on births, deaths, and later women's fertility, and on other mass social phenomena. This line of research was initiated by John Graunt, who published the first 'mortality tables' in *Observations upon the Bills of Mortality* in 1662 (Zeisel, 1974, p. 106; Lazarsfeld, 1982a/1961). He drew attention to certain recurring patterns and uniformities in these tables and thus took the first step toward using mass data to describe some underlying laws in the life of society. What primarily distinguished this line of development was the emphasis on standardized types of information. The data collected on comparable units were identical in structure. So it could be summarized in tables, compared with subsamples, and employed to say something about recurring patterns in observed social phenomena. Initially this line of research was called 'political arithmetic.' The insurance industry needed information on the average length of life in the population. Some programs to meet this demand were developed by the astronomer Edmund Haley, who in 1693 published the very first 'life tables' (on the population of Breslau in Silesia) (Lecuyer and Oberschall, 1968, p. 37). Unlike Graunt's data on London, these data additionally contained information on how old people were when they died. As a result Haley was able to calculate the 'chances of survival to any given age' (Lecuyer and Oberschall, 1968, p. 37).

This line then continued in France, where in 1750–89 the government left the initiative 'to learned societies and private individuals' (Lecuyer and Oberschall, 1968, p. 38). The challenge was accepted by the Encylopedistes. In an entry headed *Arithmétique politique*, Denis Diderot gave a detailed account of the work of William Petty in 1751. Deparcieux published 'mortality tables' in 1746. The abbé Expilly investigated numbers of births in 9000 parish records between 1762 and 1770 and in his *Geographic, Historical and Political Dictionary of*

France-based estimates of the population of France on the number of families, producing a figure of 22 million for the population in France (Lecuyer and Oberschall, 1968, p. 39). These calculations prompted further research by M. Moheau, who produced more accurate demographic calculations in the year 1778 using parish records on the number of births, broken down by sex, and parental status and with consideration of the natural and social conditions influencing maternal fertility (Lecuyer and Oberschall, 1968, p. 39). After the fall of Robespierre the French government showed a revived interest in scientific institutions and in 1795 founded the Institut National des Sciences et des Arts (Lecuyer and Oberschall, 1968, p. 40).

Meanwhile, in the second half of the eighteenth century, the ideas of Herman Conring, who had worked at the University in Helmstedt in Brunswick in the seventeenth century, began to attract attention in Germany. Conring's ideas were initially recorded by his students in Latin as *Collegium Politicalstatisticum*. He was interested in how the state functioned, and offered a description of its economic, administrative and legal system, and formal and informal relations in organizations (Lazarsfeld, 1982b, pp. 110–115). Conring's system was first introduced in the German language by Gottfried Achenwall only many decades later in 1749.

In France Pierre Simon Laplace (*Mechanique céleste* 1798), Jean Baptiste Fourier, Nicolas de Condorcet (*Mechanique sociale*), and others developed the basic elements of the theory of probability. This work motivated the young Adolph Quételet to apply the general rules of probability theory to the analysis of the human population, first in relation to physical size, then to crime rates broken down by region and age of offenders, and later to other social phenomena. Quételet talked of 'moral statistics.'

Adolphe Quételet, starting with his study *Sur l' homme et le développement de ses facultés, ou Essai de physique sociale*, *A Treatise on Man and the Development of His Aptitudes, or Essay on Social Physics* originally published in 1835, in English translation from 1842 (Quetelet, 1835/1842; Sarton, 1935), demonstrated that clear patterns can also be found in social data. He was the first to show the value of comparative statistics and the application of probability to moral and social issues (Eknoyan, 2007, p. 49). In his view there existed 'social laws' as well as natural laws. His measurements of the attributes of the human body provided evidence that mass data on humans could exhibit the same patterns as data in the natural sciences. His statistics on criminal acts classed by the sex and age of offender for individual judicial districts showed similar patterns. The concept of the 'average man' became a meaningful new idea in the social sciences, i.e., that mass data collected on a group of people and statistically processed could yield a mean (average) and margin of variation around the mean as a meaningful statement about that group (Landau and Lazarsfeld, 1968, p. 251).

The German Historical School in Economics as the Inspiration for Empirical Sociology

The German historical school in economics led by Gustav Schmoller made a crucial contribution to the development of empirical sociology. When these ideas crossed the Atlantic they proved to have a major influence, for example, on W.E.B. Du Bois' *The Philadelphia Negro* (Bulmer, 1991, pp. 171–172).

Du Bois studied economics in Berlin under Gustav Schmoller and after completing his doctorate in history at Harvard University carried out a unique study, *The Philadelphia Negro*, of the black population in a slum in Philadelphia. He drew inspiration from the method of Charles Booth, but went further, obtaining standardized data on 2400 black families in a slum in Philadelphia 'face to face' using house-to-house interviews with the inhabitants of the slum alone and without the help of inspectors (Bulmer 1991, pp. 177–179). Du Bois was an Afro-American and therefore enjoyed a high degree of trust from his respondents. In addition to this extraordinary research monograph, between 1898 and 1910 he published 12 independent and collective research studies (altogether more than 2000 pages), which dealt successively with the 10 most pressing problems of the black population in the southern US states. He established the first historically recorded sociological school with a research program at Atlanta University, organized regular scientific conferences, and founded a publication series called *Atlanta University Studies* (Bulmer, 1991, p. 184; Wortham, 2005).

The influence of the economic historical school in Germany was evident in the early stages of sociography in the works of the first systemizers of empirical evidence Gustav Schnapper-Arndt, Adolph Levenstein (Petersen, 2012, pp. 217–224), and Max Weber (Oberschall, 1965).

Another important branch of study based on empirical evidence drawn from the social world was the research of Fréderic Le Play. He based his conclusions about the social world on detailed accounts of individual families and households. He wrote very accurate and thorough monographs on the families of miners and laborers, first in France and later in other countries in Europe (Le Play, 1877–79, 1859–60), and his work has therefore been frequently considered to be the 'foundation of the monographic method.' Data about a specific miner's family, including his family budget, information on his housing, number of children, and the management of the household were all relevant for Le Play.

The Beginnings of ESR in the United States: *The Polish Peasant*, the 'Social Survey' Movement, and the Studies of the Chicago School

In the United States, ESR emerged in direct connection with the transformation of top American universities into institutions of science and research. In sociology, the first and strongest focus on empirical research emerged at the University of Chicago. As early as 1892 a Department of Sociology and Anthropology was founded at Chicago and soon afterward a program of doctoral studies was introduced by the department's head sociologist, Albion W. Small. In 1895 the department began to publish the *American Journal of Sociology* – the very first journal of sociology. In 1905 A.W. Small also cofounded the American Sociological Society (later called the American Sociological Association).

In 1908 William I. Thomas obtained what was at the time the extraordinary sum of 55 000 USD to study migration to the United States. From 1908 to 1914 he made a number of

research trips to Europe. He focused on Polish migrants, and in Poland began working with social psychologist Florian Znaniecki. Together they produced a monumental five-volume study entitled *The Polish Peasant in Europe and in America* (Bulmer, 1984, pp. 45–63). This was to provide models and inspiration for the next generation of Chicago sociologists. W.I. Thomas developed ideas about social attitudes, while F. Znaniecki made an analysis of values. In these volumes Thomas's theory of disorganization and reorganization was applied to an extensive body of empirical evidence in the *Polish Peasant* study and it was also a contribution to methodology. The biographic method used in the story of Wladek Wiszniewski, the analysis of personal documents such as letters of migrants to their families in Poland and from Poles to relatives in America, and Thomas's theory of 'four wishes,' elaborated in the book *The Unadjusted Girl*, all had a formative and long-term influence on empirical sociology at the University of Chicago. In 1938 the *Polish Peasant* study was selected by the sociological community as representative of the field and put forward for special discussion and critical analysis (Blumer, 1939).

In 1914 Robert Ezra Park joined Chicago's Department of Sociology, bringing with him experience as a journalist. In 1916 the *AJS* published his article *The City* in which he presented his vision of Chicago as a social laboratory. He founded a doctoral seminar in which he supervised doctoral students undertaking empirical field work. His closest colleague was Ernest Watson Burgess, whose strength was his concern for methodology and practicability in doctoral studies (Bulmer, 1984, pp. 94–95, 117). In 1921 R.E. Park and E.W. Burgess wrote their *Introduction to the Science of Society*, which was christened the 'green bible' by students and represented an entirely new concept in sociology textbooks. In 1925 they published *The City*, an important collective monograph that, in addition to Park's profile article *The City*, also included E.W. Burgess' theories of the concentric zones and of succession (Bulmer, 1984, pp. 154–155).

In the early twentieth century, sociology in the United States was very frequently associated with the charity work of institutions like the Russell Sage Foundation, Hull House in Chicago, and the Settlement Houses in many large cities on the east coast of the United States. Their main model for the collection and use of social data was Charles Booth and his studies. The dozens of social surveys produced by these institutions, with results of varying quality, were motivated by the desire to combat poverty, eliminate blatant social differences, and above all protect America's middle classes from the criminality and disorder that originated in the slums. Social surveys were the most common type of instrument applied in social work. In most cases social reformers used maps to identify areas in which most crime, poverty, unemployment, suicide, and other negative social phenomena were concentrated, and presented the results of their studies directly to the American public. They were consciously seeking to win public support for the adoption of legislation and measures aimed at reducing the incidence of negative social phenomena. One exceptional study in terms of its quality and its influence on society at the time was *Hull House Maps and Papers*, which was written and organized by Jane Addams and Florence Kelley. A later example was the series of Pittsburgh studies directed by Paul Kellogg (Oberschall, 1972, p. 216nn).

The principal problem of these social surveys was that none of these researchers knew how to statistically process a massive amount of individual data to arrive at demonstrable conclusions about a social group or subgroup under scrutiny. The 'technological' conditions for collecting, processing, and evaluating social survey data would only be developed in later decades.

In the meantime, the sociologists in Chicago who studied the urban population and published scientific papers and the first empirically oriented monographs conducted data collection and made generalizations from their findings without the use of social survey techniques. Focusing on firsthand data about natural social groupings, they were highly skeptical about information from individuals or individual households or families and did not use such data. In cooperation with other social sciences the Department of Sociology progressively established three monograph series, most of them published by the University of Chicago Press: a general social sciences series, a sociological series, and a series specializing in crime and youth. Thanks to the empirical research work of Chicago doctoral students coordinated by Park and Burgess, between 1923 and 1935 two dozen doctoral monographs and other work by graduates of the Chicago School of Sociology were published. The first was Nels Anderson's *The Hobo* (1923), followed by Ernest Mowrer's *Family Disorganization* (1927), Frederic Thrasher's *The Gang* (1927), *Suicide* by Ruth Cavan (1928), *The Ghetto* by Louis Wirth (1928), *The Gold Coast and the Slum* by Harvey W. Zorbaugh (1929), *Delinquency Areas* by Clifford Shaw and Henry D. McKay (1929), *The Jack-Roller* by Clifford Shaw (1930), *The Natural History of a Delinquent Career* and *Brothers in Crime* by Clifford Shaw (1931, 1932), *The Taxi-Dance Hall* by Paul Cressey (1932), and *Vice in Chicago* by Walter C. Reckless (1933). All these studies and other publications testify to the success of the Chicago School of Sociology. It had developed theories to guide its work, planned a sensitive research program, and became the first major school of sociology in the history of the field. (More details and arguments about the role of the Chicago school in the development of ESR can be found in Jerabek (2012).)

Community Studies in the United States and Europe: Middletown, Middletown in Transition, Yankey City Series, Marienthal

The year 1929 saw the publication of the first sociological bestseller in the United States: *Middletown*, by Robert Staughton Lynd and his wife Helen. This study of a small American town became the model for community studies. In 1924 and 1925 Robert and Helen Lynd spent a year in Muncia in Indiana, where they participated in the life of the community. They studied six areas of small-town life: 'getting a living,' 'making a home,' 'training the young,' 'using leisure,' 'engaging in religious practices,' and 'engaging in community activities' (Lynd and Lynd, 1929/1957, p. 4).

They used five different groups of methods and techniques to observe people's lives and study the town: (1) participation in the lives of people in the town; (2) the study of documents; (3) the independent collection and compilation of statistics; (4)

interviews; and (5) questionnaires (Lynd and Lynd, 1929, pp. 507–512). Living with families, they attended social events, parties, balls, charity events, private celebrations, and joined religious societies. They were invited into people's homes informally for tea or dinner. They or their assistants attended school assemblies, judicial proceedings, political debates and conventions, missionary meetings, lectures, working meetings, official lunches, and the annual dinners of various clubs and civic associations. They used participant observation and took detailed field notes of all of these research activities.

This book provided a comprehensive, complex portrait of a small American town. Unlike the Chicago School, the Middletown study was not concerned with urban problems. And unlike the social reform movement it was not motivated by the desire to improve social conditions. It therefore had more potential to serve as a model for university-based academic research, especially since readers of the book liked the pleasant picture of the world of a small American town (Neurath, 1987, pp. 72–75). The study increased the popularity of social research among the wider American public, and in doing so it certainly made it much easier for many universities to introduce sociology and social research into their curricula. In this sense Middletown marked an important step toward the inclusion of ESR as a legitimate part of academic sociology.

Robert and Helen Lynd returned to the same town a decade later to observe the changes that the Great Depression had brought about in the community. In 1937 they published *Middletown in Transition* (Lynd and Lynd, 1937). This time, they drew more heavily on social stratification theory. The picture of the community that they produced was much less idyllic than in the 1920s. This is evident, for instance, in a chapter devoted to a prominent family in the town and the way its influence had increased during and as a consequence of the economic depression.

The series of research surveys headed by William Lloyd Warner was another significant contribution to empirical research in the 1930s. The results of these surveys were subsequently published in five volumes between 1939 and 1960 and are most often cited collectively as the *Yankey City Series*. Compared to the clearly defined concept in *Middletown* or even the concepts of the Chicago School, the model of data collection and analysis employed in this series was less clear-cut. Nevertheless, it likewise exhibited the important feature of teamwork which, following tradition established by the Chicago School, was now a regular aspect of every empirical study as a tried and tested part of research methodology.

Some individual empirical studies also emerged in Europe. One was *Marienthal*, a study of an Austrian village with a high unemployment rate. It was carried out in the early 1930s during the great economic crisis (Jahoda et al., 1974/1933). *Marienthal* was one of the first empirical social studies to combine qualitative and statistical methods in its research design (Fleck and Stehr 2011: 26-28). The researchers carried out tasks like measure the pace at which 50 Marienthal inhabitants walked across the main square, ask inhabitants to fill in 80 individual time budgets, record 40 weekly household menus of unemployed families, and ask children about their wishes for Christmas presents. They conducted statistical analyses of the sale of expensive and cheap food items in the local shop using time series, and recorded the narratives of unemployed people about the past. Findings were collated and corroborated using a variety of different methods. Most of the data were drawn from families and individuals, but the findings were used to characterize the unemployed community of Marienthal as a whole. This study was published in 1933 in Germany, but since it was the work of three Jewish researchers it was not distributed via bookstores or libraries under the Nazi regime. It received recognition much later, when it was republished in German in 1960 by the Institut für Demoskopie in Allensbach, and then in 1971 and 1974 in English translation in London and New York (Jerabek, 2006, pp. 70–85). As an appendix, the book included Hans Zeisel's study *On the History of Sociography* (Zeisel, 1974/1933).

Street Corner Society – An Analysis of Relations in Groups of Young People

A different approach was developed by William Foote Whyte in his *Street Corner Society*. Whyte used 'participant observation' as almost his sole method of data collection. He then summarized his 4 years of observations made between 1937 and 1940 and published the book in Chicago in 1943. The monograph enriched sociological methodology by demonstrating that the almost exclusive use of qualitative research methods has the capacity to shed light on patterns in the structure of social groups. Whyte's *Cornerville* was an invented name for the Italian neighborhood in which he carried out his observations, and is almost wholly constructed from information about a gang of boys that hung out on street corners and members of an Italian community club in a slum in Northern Boston. It does not therefore present a complex picture of the urban community in that area; there is no description of family life, the way children are raised in the family, the way people make a living, or the status hierarchy in the whole population, nor is there anything about the religious life of the town or the neighborhood. The entire study is built on analysis of the relations within small social groups. It shows that no unsurpassable divide exists between 'the world of qualitative data' and 'the world of social patterns.' Qualitative methods can uncover social patterns, just as statistical methods do. They can identify frequently repeated relations among members of social groupings, and according to W.F. Whyte, "… we begin to see a pattern that we have not seen before" (Whyte, 1993/1943, p. 280). These relations in "the case study can discover uniformities that can be checked further in other case studies or experimentally and/or quantitatively" (Whyte, 1993/1943, p. 368). This was the contribution of *Street Corner Society* and W.F. Whyte to the history of ESR.

Market Research, Public Opinion, and Communication Research as Models for the Further Development of Empirical Social Research

In the 1920s large files of standardized data began to be used in market research, preelection polls, and generally in the study of public opinion and in media research. In this kind of

'survey research,' 'primary input data' on individual consumers or households, individual voters, listeners, or readers are gathered and the findings then applied to the whole social unit.

It was in market research and election polls that statistical methods were first regularly applied to process large standardized data sets about social phenomena. The approach involves interpreting the overall statistics for an aggregate of units that together make up a society or just a clearly identifiable population. These numbers can serve as indicators or values of variables for the aggregated characteristics of voters of the Republican Party, or attitudes of the readers of *Life* magazine, or attributes of behavior of Coca-Cola consumers.

This fundamental advance, which was initiated outside sociology, transformed ESR in the 1930s and 1940s. Unified data on the units that make up social formations were converted with the aid of statistical methods into a relevant statement about the whole social formation. Hitherto ESR had focused on characterization of concrete social formations – usually communities, towns religious, or ethnic communities. Rarely had it employed summarized data obtained from statistics on a set of units of a given social population. Verbal descriptions rather than statistical tabulations had been the usual practice. Robert and Helen Lynd did not calculate averages for 'working class' and 'business class' households. Even researchers in the social survey movement who worked with primary data on individual inhabitants and their households tended to use these data only in a socially cartographic way, so as to produce color banding for different rates of poverty or the different ethnic backgrounds of the majority of inhabitants in a given neighborhood.

Once the statistical processing of mass data had been introduced into ESR, the nature of the field began to change. One of the first examples of this kind of social research with scientific results was the 'RAVAG Study,' a radio audience study conducted by P.F. Lazarsfeld in 1931 and 1932 in Vienna. Lazarsfeld used a questionnaire survey. He did not employ any sophisticated sampling procedure, but nor did he use the data to represent, or as it were map, the whole audience of listeners. He received responses from 110 000 individual listeners and processed their responses by calculating 7000 simple indexes, each for an individual group of listeners and type of radio program. These (partially nonrepresentative) data were then analyzed on a comparative basis, interpretations being based on the pattern of the different values of indexes in relation to the groups of listeners (Jerabek, 2006, p. 65–70).

The frequent use of individualized data from large samples of units, usually consumers, voters, the population of a town, etc., led to the gradual development of standardized methods of questioning, to the improvement of sampling techniques, and to the development of statistical indicators to facilitate comparisons and adequate formulation of conclusions about the relationships between the studied characteristics of subsamples. Data collection methods also improved. In the 1920s and 1930s scaling methods and techniques were developed (Emory Bogardus, Rensis Likert, Charles Osgood, Louis Thurstone, Louis Guttman, Paul Lazarsfeld). Researchers gradually acquired punching (Hollerith) machines for classifying data, tabulations, and simple calculations (since World War II also used in academic social research). Computers and advanced software for social research were developed in the last decades of the twentieth century.

ESR Reformulates Its Research Questions: From Survey Research to Survey Analysis

The use of individualized data for scientific purposes in social research is associated with two large research projects conducted in the late 1930s and in the 1940s. Paul Lazarsfeld started his 'Princeton Radio Project' in 1937, and followed up his investigation at *The Bureau of Applied Social Research* in the 1940s. Samuel A. Stouffer directed and carried out the 'American Soldier' project between 1941 and 1950 (Stouffer et al., 1949).

Between 1939 and 1949 the 'Princeton Radio Project' generated a series of books: *Radio & the Printed Page* by P.F. Lazarsfeld; *Invasion from Mars* by Hadley Cantril, Hazel Gaudet, and Herta Herzog (1940); *Mass Persuasion* by Robert K. Merton; *The People's Choice* by P.F. Lazarsfeld, B. Berelson, and Hazel Gaudet (1944); and *Communications Research 1948–1949* by P.F. Lazarsfeld and F. Stanton (1949).

'American Soldier' was published in three stages. The first two parts and part three on the psychological experiments in 1949 (Stouffer et al., 1949; Hovland et al., 1949). Part four on the methodology of the research in 1950 (Stouffer et al., 1950). The fifth part titled 'Continuities in Social Research' by Robert K. Merton and Paul F. Lazarsfeld concentrated on the basic theoretical and methodological studies of R.K. Merton, P.F. Lazarsfeld, S.A. Stouffer, and other colleagues (Merton and Lazarsfeld, 1950).

Both projects were based on the idea that it is necessary to uncover, identify, and systematically verify causal relations in the collected data. The 'vote counting' model was transformed into the survey analysis model in conjunction with fundamental changes in data analysis (Coleman, 1972, p. 402). The new research question was why? – investigating the causes of observed phenomena led to a search for the real causes hidden behind the manifest data.

The Principles of Survey Analysis

The social sciences by their nature cannot engage in experimental research. Paul F. Lazarsfeld and Samuel A. Stouffer made up for this limitation with a new model of survey analysis and elaboration (Stouffer and Lazarsfeld, 1972/1937). 'Survey analysis' uses empirical evidence on the simultaneous effects of multiple independent variables on an observed dependent variable.

Survey analysis reveals the *causes* of observed differences. This approach, which distinguishes arbitrary relations from genuine (fundamental) causal relations between variables, was named and codified by Paul F. Lazarsfeld as the 'elaboration model' (Lazarsfeld, 1955/1946; Kendall and Lazarsfeld, 1950). The principle and methods of 'survey analysis' are thus only a generalization of the elaboration formula. 'Survey analysis' can essentially be described as the attempt to discover true, genuinely valid, fundamental connections between observed phenomena.

Important Empirical Social Studies in the 1930s and 1940s

In the 1930–1940s 'social survey' research advanced at other universities and state-funded and government-founded institutions. Key scholars in this sphere included George Gallup, Rensis Likert, Archibald Crossley, and Elmo Roper. Important institutions where research work that influenced the future nature of ESR was undertaken included the Gallup Organization, National Opinion Research Center in Chicago, Institute for Social Research at University of Michigan, and The Roper Center for Public Opinion Research. These institutions mainly conducted large representative surveys. Studies and publications drawing on local tradition in social survey were produced in many countries. Social research in France has been discussed by Terry N. Clark (Clark, 1967), and British investigation is mentioned by Martin Bulmer (Bulmer, 1985a, pp. 11–22). In Germany important studies were undertaken by Theodor Geiger, Ferdinand Tönnies, and the Frankfurt School, while in the United States prominent researchers in this area included Elton Mayo, Fritz J. Roethlisberger and William J. Dikson, and Gunnar Myrdal (Swedish origin). In the postwar period, it was the 'Kinsey Reports' that attracted the most interest, and the first of these was published in the period covered by this article (Kinsey et al., 1948).

Conclusion: The Relationship between Sociological Theory and ESR

ESR eventually became a recognized source of contributions to sociological theory. The process by which ESR became an established part of academic sociology took 50 years. In the initial phase of the process we find sociologists at the Chicago School using empirical data to improve social theory. The empirical data marshaled by H.W. Zorbaugh about 'natural areas' in *Gold Coast and the Slum*, Nels Anderson's observations on the roles of 'hoboes' in *Hobo* and the detailed description of the institution of dance halls in Paul Cressey's *The Taxi-Dance Hall* helped R.E. Park and E.W. Burgess in the development of their theories.

In the next phase of the evolution of ESR, statistically processed mass data on individuals and their families provided opportunities for generalizations about whole social units. Although often no link was made between empirical data and sociological theory in this phase, this phase was the essential starting point for future generalizations on the higher level of social units such as communities, audiences, etc. and the precondition for using and establishing a new type of data on lower order units, individuals and their attitudes, households and their characteristics. The 'survey research' stage assisted this development by standardizing the observed indicators, introducing sampling techniques, supporting the use of mathematical methods, and immensely advancing techniques of data collection and analysis.

The third phase of development made causal analysis its objective. Equipped with a clear idea of the goals and methods of data use, sociologists were already able to demonstrate that aggregate data were a tool and an instrument for social theory. We can understand this next stage as a kind of 'scientification of previously spontaneous development.' The model explicitly expressed the relations between the studied groups (or persons) and structured attributes of the phenomenon to be explained. Particular data obtained from individuals are a component part of the whole to which social theory refers. These data could then refer to and become instrumental in the development of the social sciences (Fleck and Stehr, 2011). Robert K. Merton made the point with P.F. Lazarsfeld, in the introduction to their jointly edited monograph *Continuities of Social Research*, when they described the combination of ESR and sociological theory as follows: "The appropriate arrangement of such data stemming from individuals, then, can provide systematic evidence on the cultural norms and social organization of groups" (Merton and Lazarsfeld, 1974/1950, p. 13).

Today the truth and legitimacy of scientifically obtained findings is often challenged. The challenge has been launched from the positions of the interpretative and constructivist visions of the world. Those who embrace these visions use stories and suggestive pictures, which they then elaborate, as a mode of persuasion. To expose these appearances as unsubstantiated is one of the tasks of science. In this situation it is becoming immensely important to defend and develop the cumulative structure of sociology as an integrated system of theoretically grounded empirical research and individual sociological theories built on or enriched by the findings of empirical research. Study of the history of ESR has been drawing attention to examples of the meaningfulness of this cumulative building of academic sociology.

Abstract

Empiricism in its many forms is united by an emphasis on the importance of experience to the formation of concepts and to the acquisition of knowledge. The foil to empiricism is rationalism, which emphasizes instead the importance to thought and knowledge of material that is in some sense independent of experience. Empiricism has been a widely discussed philosophical approach from the ancient period to the present day, providing accounts of the nature of thought and of the sources of knowledge. Empiricists have typically seen themselves as the scientist's friend, since they hold that knowledge of the world requires observation and experiment, but insofar as empiricists maintain that experience is the only source of factual knowledge, they leave themselves open to powerful skeptical arguments that seem to show that there can never be good reason to believe any claim about unobservable events or processes, and perhaps not even any claim that goes beyond what has actually been observed.

There are almost as many empiricisms as there are empiricists, but what these views or approaches have in common is an emphasis on the importance of experience to the formation of concepts and to the acquisition of knowledge. The foil to empiricism is rationalism, which emphasizes instead the importance to thought and knowledge of material that is in some sense independent of experience. The range of empiricist positions is vast, from the shocking view that all we can think or know about are our sensations to the mundane claims that experience plays some role in the formation of some of our concepts and in the justification of some of our beliefs. Empiricism of some form may seem both obviously correct and obviously the correct philosophy for science on the grounds that it is clear that one can only find out about the world by observing it; but this innocuous looking thought has been disputed, and in any case many forms of empiricism go far beyond it in their claims. It is also unclear whether empiricism ultimately supports or undermines claims to scientific knowledge.

History

Empiricism is a hardy perennial in the history of philosophy. It was extensively discussed in antiquity, often with considerable hostility. Plato disdained it, partly on the grounds that observation can only provide information about a realm of appearances less important and indeed less real than a more abstract realm that we may be able to grasp through a form of thinking that does not depend on experience. Mathematics was a model of knowledge for many ancient thinkers, and this is perhaps the area where empiricism is least plausible, since mathematical proofs do not seem to depend on observation. Nevertheless, empiricism did have defenders in the ancient world, with Epicurus often cited as its first clear exponent. He held not only that observation is the only source of knowledge about the world but that, insofar as they are taken as sources of information about the appearances of things, the senses never lie.

Empiricism also had its advocates in the medieval period. St. Thomas Aquinas wrote that there is nothing in the intellect which was not previously in the senses, though by this he meant to endorse only concept empiricism and not a strong form of knowledge empiricism. Concepts can only be formed with the help of sensory images, but some knowledge – for example, some knowledge about God – is available by means of logical argument independent of particular observations. Empiricism is perhaps most strongly associated with three philosophers of the seventeenth and eighteenth centuries: John Locke, George Berkeley, and David Hume. These British empiricists developed versions of both concept and knowledge empiricism. In some respects Berkeley (1710, 1713) can be seen as attempting to purify Locke's (1700) view of its nonempiricist elements and Hume (1739, 1777) as attempting the same for Berkeley. Both Locke and Hume appealed to Newton's achievements in physics for inspiration: Locke presented himself as Newton's underlaborer, 'clearing ground a little, and removing some of the rubbish, that lies in the way to knowledge.' Part of that ground-clearing operation consisted of a vigorous rejection of the claim that we are born with innate knowledge, a characteristic point of dispute between empiricists and rationalists (cf Mackie 1976). Hume characterized his own project more ambitiously, as an attempt to do for the human sciences ('moral philosophy') what Newton had done for the physical sciences ('natural philosophy'), by providing a theory that explained the creation and behavior of ideas. Berkeley was less influenced by the model of natural philosophy, aiming instead to combat skepticism and to support theism. The result was an exceptionally lucid statement and defense of idealism, the view that the only things that exist are minds and their contents. Locke had not taken this step, hoping to hold on to a material world even if our knowledge of its nature must be severely limited, but Berkeley argued that only idealism was compatible with the principles of empiricism. Hume was an idealist too, but made less of a fuss than Berkeley about this aspect of their philosophies, in part because Hume wished to avoid metaphysics, even of a negative sort.

In the nineteenth century, John Stuart Mill carried forward the tradition of British Empiricism from Hume, including his

[†] Deceased

idealism, though in Mill's (1872) hands the position is normally referred to as 'phenomenalism.' Mill held that physical objects are 'permanent possibilities of sensation': to say that there is a tree in the quad at a certain time is to say either that someone is having an appropriate arboreal experience at that time or that they would have had one if they had been in the quad. Berkeley famously preferred to account for the existence of the tree when no human is observing it by appealing to God's constant observation, but in one or two passages he clearly presages Mill's counterfactual alternative, which appeals to possible human observations rather than to actual divine observations.

Mill went beyond his British precursors, however, in his treatment of mathematics, the most obvious candidate for nonempirical knowledge. Most empiricists have adopted the strategy of admitting that pure mathematics is nonempirical but denying that it provides worldly knowledge, claiming instead that it tells us only about the logical consequences of our definitions. Mill, however, maintained that mathematics, however pure, is empirically based, an inductive inference from pervasive regularities in our experience, such as those involving the manipulation of objects.

Twentieth-century empiricism remained inspired by science. Logical positivists and logical empiricists saw empiricism both as a way to understand scientific claims and as a way to make philosophy itself more scientific and less metaphysical (cf. Ayer 1936). They especially pushed the conceptual side of empiricism, for example, in the verifiability theory of meaning, whose motto was that 'the meaning of an expression is its method of verification.' On this view, the experiences that would confirm a claim also tell us what it means, and a claim which no course of observation could either confirm or refute is either a mere definition or metaphysical nonsense. Empiricism in this century has also been promoted by scientists themselves, in movements such as operationalism in the physical sciences and behaviorism in psychology. Another influential empiricist strain in this period has been Pragmatism, especially as developed by the American triumvirate of William James, Charles Saunders Pierce, and John Dewey, and more recently in a radical form that rejects definitions and meanings by Willard Van Orman Quine (1951).

Concept Empiricism

Empiricism about concepts is the view that our concepts derive in some sense from our experiences. Hume offered what has come to be a canonical version of this position, arguing that all our ideas are copies of preceding impressions, meaning roughly that every concept is a faint image of the experiences that cause it. Thus, to take a favorable example, our idea of the color blue is supposed to a faint image of the particular blue experiences we have enjoyed. For Hume, the copy principle was not just a fundamental fact about our cognitive economy but also a powerful philosophical tool. Constructively, the copy principle is supposed to allow us to analyze the content of an idea or concept, since by tracing ideas back to their source impressions we determine what that content really is. Destructively, the copy principle is supposed to expose empty talk or thought, since if a putative idea has no possible source impression, it must be devoid of content. The copy principle obviously requires some general demarcation between impressions and ideas. Hume draws it subjectively, in terms of the relative 'force and vivacity' of perceptions, recognizing the vagueness of this distinction, but trusting that we will all understand the difference between the vividness of what one sees as compared with faintness of memory and imagination.

Hume's most famous applications of his copy principle were destructive, part of his program to expose the emptiness of metaphysics. Thus, although he allowed that we do have an idea of the 'necessary connection' that is supposed to glue causes to their effects, the source impression reveals this idea to be purely subjective. For that impression is merely the feeling of expectation of a familiar effect when we see a familiar cause, something that is obviously only in our minds. We cannot conceive one thing making another thing happen: all we can conceive is a pattern of objects. Indeed although Hume often did write as if we could conceive of external objects, he seems to have held that the copy principle rules out conception of these too.

Hume's antimetaphysical fervor was taken up by the logical positivists of the first half of the twentieth century. They took statements rather than ideas as the unit of analysis, and held that a statement is meaningful only if there is some specifiable experience that would verify it. They made an exception of mathematics and logic, which were allowed to count as meaningful even though not empirical, but only because they consisted of definitions and their consequences rather than substantive claims. Since philosophical truths have often been supposed to consist precisely of nonempirical truths about the world, it is not surprising that the verification principle was supposed to sweep away great swaths of traditional philosophical doctrine, not on the grounds that such claims are false, but that they are literally meaningless, just noise.

As with Hume, the logical positivist program also had a positive side: for those statements that did manage to be meaningful, their meaning comprised the experiences that would confirm them. From this it follows that all claims are claims about experiences. Some tempered this extreme view by speaking of observable states of affairs rather than experiences, thus making the data public. In the hands of some behaviorists in the philosophy of psychology, this brought about a kind of reversal of the positivists' original, experiential doctrine, since now rather than analyzing all claims as claims about experiences, experiences and other mental states are analyzed in physical terms. On this view, the real meaning of the claim that someone is happy is not that the person is enjoying a certain kind of inner life, but that they are disposed to behave in characteristically happy ways. Hostility to this position is the source of the story of the behaviorist who, upon meeting another behaviorist in the street, proclaims 'You're fine, how am I?'

Concept empiricism has been extensively criticized in both its negative and positive aspects. The demarcation that concept empiricism attempts to draw between genuine concept or meaningful statement on the one hand and nonsense on the other depends on making reasonably precise the notion of a copy of an impression or the conditions under which evidence confirms a hypothesis. This has proven remarkably difficult so that, for example, familiar accounts of confirmation have been shown to have the consequence that everything is evidence for anything else, a result that would make all statements meaningful and is anyway obviously false. The other conspicuous

weakness of concept empiricism concerns the specific meanings it attributes to statements that it rightly classes as meaningful. The attempt to reduce the meaning of a statement to the evidence that would support it typically both attributes meaning the statement does not have and leaves out meaning it does have. This comes out clearly in the case of scientific hypotheses that traffic in unobservable entities and processes. A hypothesis about the behavior of subatomic particles does not include as part of its *meaning* the diverse and indirect kinds of empirical evidence in its favor, while that meaning does include claims about unobservable particles.

Knowledge Empiricism

Knowledge empiricism is the view that all knowledge of the world is based on experience. Put negatively, this is the denial of a *priori* knowledge of the world. Empiricism here opposes rationalism, according to which the fundamental source of knowledge of the world is reason, not experience.

Critics of knowledge empiricism generate putative examples of a *priori* knowledge. Empiricists deal with these cases in several ways, claiming either that the statement in question cannot be known a *priori*, because it is unknowable altogether or knowable but only through experience, or that that the statement does not really provide knowledge *of the world*. Thus, when René Descartes, the great seventeenth century rationalist, claimed to know *a priori* of his own existence, Hume could respond that the only knowledge one has of oneself is of one's experiences, which are known through themselves. Mathematical knowledge is another popular area for rationalists' examples of the *a priori* although, as we have seen, Mill claimed that even this knowledge is ultimately empirical, resting on observations of the result of adding together and dividing apart physical objects. The more common empiricist treatment of mathematical knowledge, however, is to admit it does not depend on specific experiences but to deny that it is about the world. Both Hume and the logical empiricists admit that definitions or analytic truths – such as that a bachelor is an unmarried man – can be known to be true without experience, but maintain that these statements have no factual content. They then analyze mathematical axioms as definitions and treat everything that is derived from them as analytic truths which can be known without experience but tell us nothing about the world.

Empiricism and Scientific Knowledge

Alongside the question of whether there can be any knowledge independent of experience is the question of how far empirical knowledge may extend beyond the experience upon which it is based. Since Hume's seminal discussion of the problem of induction, it has become difficult to see how knowledge can extend beyond actual experience at all. It is neither surprising nor worrying that any nondemonstrative inference from experience might in principle go wrong; but Hume gave a remarkably resilient argument that we can have no reason whatever for extrapolating in one direction rather than in another, even when dealing with everyday claims about the immediate future or the unobserved past and present. The nub of the problem is that any justification for the future success of our methods of prediction or extrapolation seems itself to rely on such a method, leaving us arguing in what is apparently a vicious circle, not unlike trusting someone solely on the grounds that he or she claims to be trustworthy. Thus empiricism has been a friend to the skeptic: if Hume is right, we have no more reason to trust the most sophisticated scientific predictions than tea leaves or entrails.

Even empiricists who, ignoring the Humean problem of induction, help themselves to inferences from past to future observations have had the greatest difficulty in showing how scientific knowledge is possible, since scientific theories appear to traffic in claims about entities and processes that are un observable, not just unobserved. As we have seen, this is denied by the concept empiricists, for whom no claims about the unobservable can even be formulated, but few recent empiricists have been willing to go down this road. Instead, they have had to face the problem of the underdetermination of theory by data, developed with special force in the work of Pierre Duhem (1954) and Willard Van Orman Quine (1975).

The problem is that no matter how much evidence there is in favor of a particular scientific theory, there exist in principle many other theories, incompatible with the first yet compatible with all the evidence. This creates an epistemic stalemate that seems to block warranted inference to any claim that goes beyond what is observable.

Empiricists have attempted to deal with the underdetermination problem in a number of ways. Karl Popper (1959) adopted a radical solution that was designed to solve the Humean problem of induction as well. It was to deny that scientists need to indulge in nondemonstrative inferences at all. Instead, they are to attempt to refute their theories and then replace them by better ones, where this process relies only on a deductive inference from the falsity of a prediction to the falsity of the theory that entailed the prediction. This is empiricism in the sense that the rejection of a theory is determined by observational data. Popper is one of the few philosophers of science to have attracted the respect of a significant number of practicing scientists, probably because scientists appreciate being reminded of the importance of considering what sort of results would tend to undermine a hypothesis, but Popper's view has been severely criticized by philosophers. Falsifying an interesting and successful scientific theory is not nearly as straightforward as Popper would have scientists pretend. Moreover, even if Popper's methodology could be put into practice, it would still be a form of skepticism, since according to him we never have any reason whatsoever to think that any scientific theory or prediction is even approximately correct, nor can we have any reason to believe any claim about the future.

Empiricism continues to play an important role in the study of knowledge within science studies. One example is the 'strong program' in the sociology of knowledge, which rests on a kind of psychological empiricism. As David Bloor (1991) puts the matter, the strong program assumes that perception and thought are distinct but asymmetrically related: perception influences thought more than thought influences perception. Within the philosophy of science, a recent empiricist approach to scientific knowledge and the underdetermination problem is Bas Van Fraassen's constructive empiricism. Van Fraassen (1980) introduces a technical sense of 'acceptance,' where to accept a scientific theory is not to believe that it is true, but only that it is empirically adequate, where a theory is empirically

adequate just in case everything it says about what is observable is true.

Constructive empiricism is the view that the aim of science is to discover theories that are empirically adequate, not theories that are true. The content of the theory that goes beyond its empirical claims is to be regarded as a model which may serve its function of generating true predictions without itself being a true representation of an invisible realm. Constructive empiricism thus appears to solve the underdetermination problem, since although the theories underdetermined by the data will be incompatible with each other, their empirical consequences, which is all the constructive empiricist would have us believe, may be compatible.

Constructive empiricism can thus be seen as a form of moderate skepticism, but it is still too skeptical for those who think that knowledge or at least reasonable belief about unobservable entities and processes is possible. Constructive empiricism also faces the difficulty of providing a nonarbitrary distinction between what is observable and what is not, a tricky problem faced in one form or other by almost all forms of empiricism.

Abstract

Employment regulation consists of the legal rules and institutions that constitute, govern, and structure the employment relationship. Until recently, most industrial countries had employment regulation that provided most employees with job security and an adequate package of social protection. However, these regulations have been relaxed in recent years as employers have moved away from hiring employees into long-term employment relationships and have created many types of short-term employment relationships instead. The decline of the standard form of employment and the regulatory regime that supported it has given rise to a number of controversies involving employment regulation. In addition, the spread of global trade and the diffusion of production around the world have put pressure on industrial countries to dilute their employment regulation and lower their labor standards. However, as global production and trade continue to proliferate, social pressures are building for more labor law protections both in the developed and in the developing world. Hence employment regulation is not likely to disappear, but it will be transposed as part of the emerging international regime.

Employment regulation consists of the legal rules and institutions that constitute, govern, and structure the employment relationship. Employment regulation potentially affects all aspects of employment – it determines whether an employee has job security, the minimum amount an employee must be paid, the safety and health conditions at the workplace, the right to vacation pay, sick leave pay, or other benefits, protection from discrimination on the basis of gender, race, ethnicity, religion, age, or personal attributes, the minimal age for employment, the age and terms of retirement, the provision of job training, protection from intrusive surveillance on or off the job, and many other aspects of the employment relationship.

The content of employment regulation also determines the parties' bargaining power vis-à-vis each other (Hale, 1923). For example, legal rules determine whether workers are free to join together into unions or whether such actions constitute unlawful conspiracies, whether and under what circumstances they may lawfully strike and picket, and whether they can use secondary pressure or appeals to the general public to support their position. Because bargaining power ultimately determines employees' wages, the legal rules that govern the employment relationship have powerful distributional consequences. For this reason, the content of employment regulation has always been a hotly contested and intensely politicized issue.

Employment regulation occurs by means of legislative action, judicial ruling, administrative action, contract, or custom. It is often assumed that employment regulation refers to affirmative interventions by the state into the employment relationship by means of statutes, administrative regulations, executive orders, or other acts of positive law. That assumption is incomplete. Employment regulation also takes place through the background contracting rules with which a buyer and a seller of labor power – that is, and an employer and an employee – form an employment relationship. For example, some countries treat the individual employment contract as a conventional contract that imposes affirmative duties on both the employer and the employee. For this reason, in many parts of Europe and Latin America, an employer violates the employment contract by firing an employee without good cause. In the United States, in contrast, the background default form of the employment contract is an at-will contract, that is, an arrangement in which an employee can be fired at any time for any reason (Stone, 2007).

In most industrial nations, there are two types of labor regulations – regulations that establish specific terms of the wage bargain and regulations that legally empower labor and management to engage in self-regulation. Direct employment regulation includes statutes that set minimum wages and maximum hours of work, mandate certain health and safety standards, regulate employer-based pensions and health insurance, and provide anti-discrimination protections. Legally empowered self-regulation involves statutes or doctrines that permit employees to form unions and bargain with employers for the terms and conditions of employment. Most Western countries have both types of employment regulation, but they differ as to which type is dominant in their labor relations system (Kahn-Freund, 1983). For example, most continental European countries have detailed legal codes that specify many terms of the employment relationship such as mandated hours of work, safety conditions, and childcare leave policies. Most also have laws that establish criteria for a lawful labor union and authorize such unions to engage in collective bargaining to determine certain terms and conditions of work. Many also have specialized labor courts to enforce both collective and individual employment rights. Moreover, in Germany and France, terms negotiated between unions and employers can be transformed into regulations applicable to entire industries or regions of the country (Weiss, 1987). In contrast, Great Britain relies primarily on the common law to regulate the employment relationship, and leaves many important employment terms to the parties to negotiate. In some instances, this leaves agreements outside the law altogether (Wedderburn, 1986).

Countries also differ in terms of what kinds of rights, privileges, and protections they give to organized labor. Some countries give very broad protection to collective action such as organizing, strikes, and picketing, while some do not.

While employment regulation creates the respective bargaining power of labor and management, it also reflects each side's relative power in the political process. Employers and unions operate as pressure groups, lobbying directly or indirectly galvanizing public opinion to shape the substantive law of employment in ways that will give them advantage. Judges and legislatures are, at least in part, responsive to the competing demands of employers and employees when they decide cases and enact employment-related statutes.

Employment Regulation of the Standard Contract of Employment

Despite differences between countries, a standard contract of employment became the norm in large manufacturing firms throughout much of the twentieth century. This standard contract provided employees with job security, decent wages, a rising trajectory for promotions and raises, and a generous package of health, retirement, and other job-linked benefits. While the standard contract was never universal, it covered large portions of the workforce in industrialized countries and became the prevailing norm by the middle of the twentieth century (Stone and Arthurs, 2013).

The standard contract of employment did not emerge fully formed: It was devised by industrial relations theorists, implemented by large manufacturing firms, bolstered by pressures from unions, and fortified by the various labor law regimes in the industrial nations. Gradually over the first half of the twentieth century, legal regimes that regulated employment emerged in various countries that adopted this standard employment model as their template. As a result, by the mid-twentieth century, most industrial nations had labor law systems that provided extensive protection for job security either by statute, contract, or custom. Most countries also had laws that required employment relationships to conform to the standard contract and that placed strict limits on the ability of firms to utilize temporary workers, short-term workers, or independent contractors. In addition, most had laws fostering company and/or industry-level collective bargaining that assumed that unions represented members who had long-term jobs.

To be sure, the standard employment contract was never universal. In each country, it covered different proportions of the workforce, and within the workforce, different sectors and segments. It was more characteristic of large manufacturing enterprises and the public sector than it was of small enterprises or the service sector, was more likely to cover men than women, and was more available to well-established populations than to recent immigrants or racial and ethnic minorities. Nonetheless, allowing for all these variations, the standard employment contract was both the paradigm that informed much labor policy and practice and the ideal to which these aspired.

Although the basic shape of the standard employment contract was prevalent in industrial countries for the last part of the twentieth century, the legal regimes that emerged to support it differed markedly from country to country. In some countries, the state mandated job security by statute. In others, the standard contract of employment was imposed by mandatory terms that were incorporated into the individual contract of employment. In yet others, job security was negotiated as part of a state-supported system of collective bargaining. And in some, it was a product of custom reinforced by legal mechanisms.

Until recently, extensive job security protections in certain countries such as France, Italy, and Spain gave workers nearly impregnable job security and made it extremely difficult for employers to fire workers or to downsize their workforces, even in dire economic exigencies. Furthermore, in Germany, the Netherlands, and other continental European countries, statutory job security protection was fortified by strong centralized unions, whose power was also protected by law as a matter of state policy.

In contrast, in the United Kingdom and the United States, the individual contract of employment was practically an oxymoron. Under the at-will contract rule that prevails in those countries, an employee can be fired at any time for any reason. Furthermore, the employer can change the terms of the contract at any time. Because the employment relationship has neither fixed duration nor fixed terms, it is somewhat misleading to call it a contract at all. The United Kingdom mitigated the harshness of the at-will rule with legislation that gave compensation to workers who were unfairly dismissed. In the United States, a few states have adopted common law doctrines to provide some unfair dismissal protection, but these are the exceptions, not the rules. Rather, unions in the United States often provided job security for their members by negotiating contractual provisions that specify that an employer can only dismiss an employee for 'just cause.' However, because union density has been comparatively low and steeply declining, this type of contractual protection is becoming rare (Stone, 2013a).

Countries also differ as to the way in which aspects of employment other than job security are regulated. In some countries, the state uses general tax revenues to provide a broad spectrum of work-related benefits such as skills training, employment insurance, job placement centers, day care, as well as universal benefits to workers and others, such as health care, social housing, and education. In other countries, some of these benefits are provided through contributory arrangements to which both employers and employees are required to contribute. In some, these benefits are provided by employers under compulsion of law, or in response to pressures brought by unions through collective bargaining or as part of a strategy to recruit and retain a loyal and productive workforce.

The Changing Nature of Employment

Recently employers throughout the industrial world have moved away from hiring employees into long-term employment relationships and have created many types of short-term employment relationships instead. They have increased the use of 'atypical' employees – those lacking some or all the elements of the standard contract. They have also increased the use of independent contractors and individuals leased from temporary employment agencies. Furthermore, in all industrial countries, job security has been declining (Stone, 2013b); in fact, many of these regimes recently have

changed their laws specifically to relax job security protections (Stone and Arthurs, 2013).

The decline of the standard form of employment and the regulatory regime that supported it have given rise to a number of controversies involving employment regulation. Some of the current controversies concern the following issues:

1. Who is an 'employee' under the labor laws, and hence entitled to employment protection? Should some employment protections be accorded to individuals who have no discernible employer, and if so, which protections, and to which individuals should they apply?
2. What are the respective roles of the state and employers in ensuring job security and social protection?
3. Can unions operate effectively in the workplace if employers no longer provide long-term jobs? Are there new roles for unions at the political level, and if so, can unions be effective in the political rather than the workplace realm?
4. Should there be transnational labor regulation to prevent firms from undermining national labor standards by relocating production to countries that have the lowest levels of labor standards?

Who is an 'Employee' under the Labor Laws, and Hence Entitled to Employment Protection?

Traditionally employment regulation has been applicable only to individuals who are 'employees.' The term 'employees' refers to an individual in an employment relationship with an employer. The law assumes that the employment relationship is well defined. Hence employment regulation does not apply to individuals who provide services for a fee, whether as business entities or independent contractors. When disputes arise, courts apply either a 'right to control' or an 'economic dependency' test to determine whether an individual was an 'employee' for purposes of the labor laws (Davidov, 2005; Stone, 2006).

In recent years, the line between employee and independent contractor has become blurred. Increasingly, employers utilize the services of individuals whom they characterize as independent contractors, even when the employer exercises considerable control over the work tasks of the individual so retained. Numerous other work relationships have arisen that do not fit the traditional employee–independent contractor dichotomy. For example, on-call workers, zero-hours workers, agency temporary workers, unpaid interns, volunteers, franchisees all pose problems when using traditional analyses to determine employee status (Hyde, 2006).

Adding to the difficulty in defining employees is the fact that many employers no longer seek to control the precise method of task execution by their 'employees.' Under current human resource practices, employers often delegate increasing amounts of discretion to employees, thus defying any mechanistic application of the 'right to control' test used for determining employee status (Stone, 2004).

Often employers today seek to label individuals as independent contractors to avoid the obligation to comply with employment regulations. For example, several years ago, trucking companies in the United States began to convert their drivers into owner-operators, but often required the drivers to lease the company's trucks, wear company-provided uniforms, drive routes the company orders them to drive in the sequence and on the timetable the company mandates, and serve exclusively the company's clients. However, as independent contractors, the drivers were not entitled to minimum wage and overtime pay, were not covered by unemployment insurance, workers compensation, or social security, and were legally precluded from belonging to a union.

The use of phony 'independent contractors' has spread far beyond the trucking industry, both in the United States and elsewhere. Today the practice is prevalent for firms that use the services of janitors, construction workers, IT workers, secretarial workers, hospital orderlies, and even machinists inside factories. In the United States, the claims by employees that they have been 'misclassified' as independent contractors are the most frequently litigated employment disputes today.

In recent years, courts, legislators, and scholars in many countries have debated the issue of who is an 'employee.' In the United Kingdom, Sweden, Germany, and Canada, courts have created an intermediate category between employee and independent contractor called 'semi-dependent worker' or 'dependent contractor' that enables individuals who are dependent on a single employing entity to enjoy some employment protections (Davidov, 2005). Some scholars are also attempting to redefine the concept of employment to embrace not only an immediate employment status, but also an individual's entire employment relationship (Freedland and Kountouris, 2011).

What Are the Respective Roles of the State and Employers in Providing Job Security and Social Protection?

Given the decline of long-term jobs and the rapid growth of short-term and atypical forms of employment, some commentators have proposed that there be legal regulation to ensure job security. Some, for example, propose that the right to a decent job be treated as ahuman right, enforceable under the International Covenant on Economic, Social and Cultural Rights (Mantouvalou, 2014). Others advocate a return to the twentieth century labor law regimes of continental Europe, in which employees had strong dismissal protection even in the face of severe employer financial distress (Njoya, 2012). However, many have criticized rigid job security protection because it deters employers from hiring employees. There have been efforts to enact legislation that would guarantee work to all who want it by making the government serve as employer as last resort, but these efforts have not been succeeded (Stone, 2014a).

Because long-term jobs are declining, social protections that are linked to employment are also declining in prevalence and scope. Until now, countries have differed as to which types of social protection are provided by employers and which are provided by the state. There are two basic types of systems for providing for unemployment, health insurance, old age security, and other social protection. One is a contributory social insurance program to which employees, employers, and sometimes the state, contributes. An example is found in the Nordic countries, where unemployment insurance funds, administered by the unions, provide generous benefits. Employees voluntarily contribute to the funds, and the state provides additional revenues. The other commonly used mechanism for providing social protection is by means of

universal schemes paid out of general tax revenue. In many countries in Europe health insurance, industrial accident insurance, paid pregnancy leave, and pensions are provided by the state as a universal benefit. However, both contributory and universalistic systems are typically based on employment status. That is, an individual has to have been employed for a specific period of time to qualify for benefits.

The employment-linked nature of social protection has become problematic in a labor market in which individuals no longer have long-term jobs. Because many employees now make frequent moves between employers, and transition periodically from employment to self-employment, training, unemployment, and care work, the employment-linked nature of the social safety net is no longer adequate. Many scholars have proposed alternative arrangements for providing social benefits that do not depend upon long-term employment (Supiot, 2001). For example, Australia has devised a system of social protection that is not linked to employment at all. There the state provides a generous means-tested flat-rate benefit, financed by general tax revenues raised through a progressive income tax, to individuals who are out of work for any reason (O'Donnell, 2013).

Can Unions Operate Effectively in the Workplace If Employers No Longer Provide Long-Term Jobs? If Not, are There New Roles for Unions at the Political Level?

For most of the twentieth century, labor unions have focused on improving wages and conditions for workers. In many places, unions operated at the workplace level and negotiated specific terms for workers of a particular firm. In some countries, unions have also operated at the national or industry level to negotiate terms and conditions that apply across numerous firms. Overall, unions were created by, and supported by, employees who had a long-term investment in their jobs. Thus, because long-term employment has declined, unions have lost much of their effectiveness in the workplace.

New types of labor organizations are developing to further the interests of workers across workplaces or for workers who have multiple and changing employers. For example, in many cities in the United States, unions have formed coalitions with community groups to enact living wage ordinances to improve labor standards for low-wage public sector employees citywide. Presently there are living wage ordinances in over 40 United States cities. Some of these ordinances not only require employers to pay minimum wages at a level that is above the national statutory rate but also require employers to provide their workers with health insurance or other benefits (Stone and Cummings, 2011).

In Japan, there has been an explosion of nontraditional forms of labor organizations. In many places there are city unions that pressure employers in an entire metropolitan area around work-related concerns. There are also women's unions organized to further interests of women workers, and ethnically specific unions to assert pressure on behalf of specific ethic groups. A particularly dynamic form of nonconventional union in Japan is the community union. These unions include part-time workers, temporary workers, immigrant workers, and others who are generally excluded from the traditional enterprise-based unions. In 1990, the Community Union National Network was formed to bring together 72 community unions that were operating in 30 different prefectures. These unions have continued to grow in membership and numbers, and some have affiliated with the National Confederation of Trade Unions or the Japanese Trade Union Congress (Nakamura and Nitta, 2013).

Some commentators have argued that unions have lost much of their effectiveness at the workplace level, and so in spite of that they should devote more efforts to advocating for the interests of workers in the political action. Although unions have always been involved in politics to some extent – more directly in some countries than in others – these commentators advocate that unions shift their emphasis because many important issues of employment regulation are decided at the political level.

In the United States, unions have attempted to compensate for decreased membership and power in the workplace by increasing their expenditures and efforts in the political domain in recent years. However, the ability of unions to operate effectively in the political process has been constrained both by court decisions and by legislative action at the state level (Sachs, 2013).

It is not necessarily the case that unions must choose between seeking power in the bargaining arena and power in the political arena. In the Nordic countries, for example, unions play a large role in the political process and in shaping employment legislation, and they use their power in the political arena to strengthen and reinforce their role in the workplace (Due and Madsen, 2008; Jorgensen, 2002).

Should There be Transnational Labor Regulation to Prevent Firms from Undermining National Labor Standards by Relocating Production to Countries That have the Lowest Levels of Labor Standards?

At present, one of the most pressing issues for employment regulation lies at the transnational level. Businesses that are faced with increased competitive pressures from global trade or presented with enhanced opportunities for direct foreign investment are eager to reduce their labor costs. When they can relocate their operations from restrictive regulatory environments less restrictive ones to lower their labor costs, they do so. To prevent capital flight and to attract jobs, countries engage in regulatory competition by lowering their labor standards regulations and by nonenforcement of the employment regulations they have. Thus firms move around the globe like checkers, jumping from place to place to avoid onerous employment laws, and generating a downward spiral of deregulatory reforms. This dynamic is termed the 'race to the bottom' for labor standards.

Labor organizations and policy-makers in many countries have made numerous proposals for a regime of transnational labor regulation that could impose some minimum global labor standards. Some types of transnational labor regulation have emerged through trade agreements such as the European Union and the Side Agreement to the North American Agreement on Free Trade. In addition, some states have taken unilateral action to condition trading privileges on labor standards, and some companies have adopted voluntary company codes of conduct to prevent labor abuses

(Stone, 1999, 1995). Although each of these mechanisms has had some success in raising labor standards in specific instances, they have not deterred companies from diverting jobs to low-wage companies nor protected workers in those countries against unsafe conditions or abusive labor practices. In part, the reason for the partial success is that each of these efforts relies on a specific country, trade block, or multinational company to serve as the promulgator and enforcer of labor standards; they do not build a universal transnational consensus.

There are several approaches for developing a more universal mechanism for enforcing labor standards at the international level. First, some have called for more powerful transnational institutions that have the power and authority to impose hard law solutions – something like the International Labor Organization (ILO) but with teeth. The argument is that the ILO, or the World Trade Organization (WTO), or some kind of global labor tribunal with sufficient power and legitimacy, should set minimal standards, define fundamental labor rights, and set up an enforcement mechanism akin to the International Criminal Court to adjudicate and remedy allegations of breaches (Barry and Reddy, 2006; Hyde, 2009).

Second, some have argued not for establishing a floor for labor standards, but rather for policies to bolster the safety net so that everyone can have a decent standard of living regardless of trends in labor markets. One scheme of this type is the proposal for a basic income, sometimes called a 'citizenship grant,' which is a socially adequate level of support made available to every citizen without any work requirement or other type of strings attached (Standing, 1999).

A third approach is to advocate policies that encourage a race to the top that can counterbalance a race to the bottom. There have been several different proposals for mechanisms to facilitate a race to the top (Trubek and Trubek, 2005).

Given today's political landscape, each of these proposals faces daunting obstacles. Nonetheless, each of these approaches has not only been theorized and debated in the scholarly literature – each has actually been implemented in some places (Stone, 2014b).

Nonetheless, most trade experts remain adamant that labor considerations should not enter into trade agreements (Bagwati, 1994). Thus the world trading system is evolving without any effective mechanism to protect labor standards, thereby creating an unregulated global labor market in which companies can easily avoid domestic labor unions and national labor regulation. The resulting international race to the bottom will not only depress labor standards in the developed countries, it will also weaken the political influence of labor unions to sustain high domestic labor standards or to press for international ones (Stone, 1995). Given the wide disparities in labor standards across nations, workers in the developed world will be the first ones to suffer from the unfettered quest for corporate profits. However, workers in the developing world will ultimately experience the harshness of a labor market unmediated by redistributive and empowering employment regulation.

The present-day commitment of free trade advocates to separate social concerns from trade is a new formalism that has operated to prevent transnational agencies from addressing social concerns, raising standards, and redressing inequalities. However, as global production and trade continue to proliferate, social pressures are building for more labor law protections both in the developed and in the developing world. Hence employment regulation is not likely to disappear, but it will be transposed as part of the emerging international regime (Stone, 2014b).

Empowerment Evaluation

David M Fetterman, San Jose, CA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

Empowerment evaluation is an evaluation approach designed to help communities monitor and evaluate their own performance. It is also used to help groups accomplish their goals. Empowerment evaluation focuses on fostering self-determination and sustainability. It is particularly suited to the evaluation of comprehensive community-based initiatives or place-based initiatives.

Definition

Empowerment evaluation is the use of evaluation concepts, techniques, and findings to foster improvement and self-determination (Fetterman, 1994). An expanded definition is: Empowerment evaluation is an evaluation approach that "aims to increase the probability of achieving program success by (1) providing program stakeholders with the tools for assessing the planning, implementation, and self-evaluation of their program, and (2) mainstreaming evaluation as part of the planning and management of the program/organization" (Wandersman et al., 2005).

Background

Empowerment evaluation was introduced to the field of evaluation in 1993 (Fetterman, 1994). It has been used in remote Amazonian regions as well as corporate offices of Hewlett-Packard in the Silicon Valley. Empowerment evaluation has been used by NASA/Jet Propulsion Laboratory to educate youth about the prototype Mars Rover, townships in South Africa to create sustainable community health initiatives, the US Department of Education's Office of Special Education and Rehabilitation Services to foster self-determination, and with Native American tribes to build technological and economic infrastructures on reservations. It has also been used to address academic distress (Fetterman, 2005b), accreditation in higher education (Fetterman, 2001, 2012), minority tobacco prevention (Fetterman, 2005b; Fetterman et al., 2014a), and medical education (Fetterman, 2009; Fetterman et al., 2010). Empowerment evaluation is international in scope. It is applied in over 16 countries. A sample of the literature situating empowerment evaluation in the field of evaluation is listed below: Alkin and Christie (2004), Altman (1997), Brown (1997), Cousins (2005), Donaldson (2005), Fetterman (1995, 1997, 2001), Fetterman et al. (1996, 2014b), Fetterman and Wandersman (2005, 2007), Fetterman et al. (2010), Patton (1997a, 2005), Scriven (1997, 2005), Sechrest (1997), Stufflebeam (1994), and Wild (1997).

Theories

Empowerment evaluation is guided by empowerment theory, self-determination theory, process use, and theories of use and action. *Empowerment theory* focuses on gaining control of resources in one's environment. It also provides a guide for the role of the empowerment evaluator. *Self-determination* theory highlights specific mechanisms or behaviors that enable the actualization of empowerment. *Process use* cultivates ownership by placing the approach in community and staff members' hands. Finally, the alignment of *theories of use and action* explains how empowerment evaluation helps people 'walk their talk' and produce desired results.

Empowerment Theory

Empowerment theory is about gaining control, obtaining resources, and understanding one's social environment. It is also about problem solving, leadership, and decision making. It operates on many levels, and distinguishing between empowering processes and outcomes is critical. According to Zimmerman (2000):

> Empowerment processes are ones in which attempts to gain control, obtain needed resources, and critically understand one's social environment are fundamental. The process is empowering if it helps people develop skills so they can become independent problem solvers and decision makers. Empowering processes will vary across levels of analysis. For example, empowering processes for individuals might include organizational or community involvement, empowering processes at the organizational level might include shared leadership and decision making, and empowering processes at the community level might include accessible government, media, and other community resources.

Empowerment theory processes contribute to specific outcomes. Linking the processes to outcomes helps groups specify their chain of reasoning. Zimmerman (2000) provides additional insight into the outcome level of analysis to further explicate empowerment theory:

> Empowerment outcomes refer to operationalization of empowerment so we can study the consequences of citizen attempts to gain greater control in their community or the effects of interventions designed to empower participants. Empowered outcomes also differ across levels of analysis. When we are concerned with individuals, outcomes might include situation-specific perceived control, skills, and proactive behaviors. When we are studying organizations, outcomes might include organizational networks, effective resource acquisition, and policy leverage. When we are concerned with community level empowerment, outcomes might include

evidence of pluralism, the existence of organizational coalitions, and accessible community resources.

Role

Zimmerman's (2000) characterization of the community psychologist's *role* in empowerment activities is similar to the role of the empowerment evaluator.

> An empowerment approach to intervention design, implementation, and evaluation redefines the professional's role relationship with the target population. The professional's role becomes one of collaborator and facilitator rather than expert and counselor. As collaborators, professionals learn about the participants through their cultures, their worldviews, and their life struggles. The professional works *with* participants instead of advocating *for* them. The professional's skills, interest, or plans are not imposed on the community; rather, professionals become a resource for a community. This role relationship suggests that what professionals do will depend on the particular place and people with whom they are working, rather than on the technologies that are predetermined to be applied in all situations.

Additional literature on empowerment theory is provided by Zimmerman (2000), Zimmerman et al. (1992), Zimmerman and Rappaport (1988), and Dunst et al. (1992).

Self-Determination

Mithaug's work in this area is typically referred to as self-regulation theory, with self-determination as a guiding concept in his work. For the purposes of clarity and as it relates to instructing empowerment evaluation, self-determination is being used as the umbrella term in this discussion. Self-determination is defined as the ability to chart one's own course in life. It consists of numerous interconnected capabilities, such as the ability to identify and express needs; establish goals or expectations and a plan of action to achieve them; identify resources; make rational choices from various alternative courses of action; take appropriate steps to pursue objectives; evaluate short- and long-term results, including reassessing plans and expectations and taking necessary detours; and persist in the pursuit of those goals. A breakdown at any juncture of this network of capabilities – as well as various environmental factors – can reduce a person's likelihood of being self-determined (see also Bandura (1982) for more detail on issues related to self-efficacy and self-determination). Dennis Mithaug (1991, 1993) has provided extensive work on the topic, focusing on individuals with disabilities. Fetterman and Mithaug's Department of Education work on self-determination and individuals with disabilities provided additional clarity to the concept. Self-determination mechanisms help program staff members and participants implement an empowerment evaluation.

Process Use

Process use assumes that the more that people conduct their own evaluation, the more they own them. The greater the sense of ownership, the more likely people are to consider their findings credible and act on their own recommendations. Empowerment evaluation places evaluation in the hands of community and staff members to facilitate ownership, enhance credibility, and promote action. In addition, a byproduct of this experience is that people learn to think evaluatively (Patton, 2002). This makes them more likely to make decisions and take actions based on their evaluation data.

Theories of Action and Use

Theories that enable comparisons between action and use are essential. Empowerment evaluation relies on the reciprocal relationship between theories of action and use at every step in the process. A *theory of action* is the espoused operating theory about how a program or organization works. This theory of action is compared with a theory of use. The theory of use is the actual program reality, the observable behavior of stakeholders (see Argyris and Schon, 1978; Patton, 1997b). People engaged in empowerment evaluations create a theory of action and test it against the existing theory of use. Because empowerment evaluation is an ongoing and iterative process, stakeholders test their theories of action against theories of use during various microcycles to determine whether their strategies are being implemented as recommended or designed.

These theories are used to identify gross differences between the ideal and the real. For example, communities of empowerment evaluation practice compare their theory of action with their theory of use to determine whether they are even pointing in the same direction. Three common patterns that emerge from this comparison include *in alignment*, *out of alignment*, and *alignment in conflict*. In alignment is when the two theories are parallel or pointed in the same direction. They may be distant or close levels of alignment, but they are on the same general track. Out of alignment occurs when actual practice is divergent from the espoused theory of how things are supposed to work. The theory of use is not simply distant or closely aligned, but actually off target or at least pointed in another direction. Alignment in conflict occurs when the theories of action and use are pointed in diametrically opposite directions. This signals a group or organization in serious trouble or self-denial.

After making the first-level comparison, a gross indicator, to determine whether the theories of action and use are even remotely related to each other, communities of empowerment evaluation practice compare their theory of action with their theory of use in an effort to reduce the gap between them. This assumes they are at least pointed in the same direction. The ideal progression is from distant alignment to close alignment between the two theories. This is the conceptual space where most communities of empowerment evaluation practice strive to accomplish their goals as they close the gap between the theories. The process of empowerment embraces the tension between the two types of theories and offers a means for reconciling incongruities.

Principles

Empowerment evaluation is guided by 10 specific principles (Fetterman and Wandersman, 2005: pp. 1–2, 27–41, 42–72). They include:

1. Improvement – Empowerment evaluation is designed to help people improve program performance; it is designed to help people build on their successes and reevaluate areas meriting attention.
2. Community ownership – Empowerment evaluation values and facilitates community control; use and sustainability are dependent on a sense of ownership.
3. Inclusion – Empowerment evaluation invites involvement, participation, and diversity; contributions come from all levels and walks of life.
4. Democratic participation – Participation and decision making should be open and fair.
5. Social justice – Evaluation can and should be used to address social inequities in society.
6. Community knowledge – Empowerment evaluation respects and values community knowledge.
7. Evidence-based strategies – Empowerment evaluation respects and uses the knowledge base of scholars (in conjunction with community knowledge).
8. Capacity building – Empowerment evaluation is designed to enhance stakeholders' ability to conduct evaluation and to improve program planning and implementation.
9. Organizational learning – Data should be used to evaluate new practices, inform decision making, and implement program practices; empowerment evaluation is used to help organizations learn from their experience (building on successes, learning from mistakes, and making midcourse corrections).
10. Accountability – Empowerment evaluation is focused on outcomes and accountability; empowerment evaluation functions within the context of existing policies, standards, and measures of accountability; empowerment evaluations ask: did the program accomplish its objectives?

Empowerment evaluation principles help evaluators and community members make decisions that are in alignment with the larger purpose or goals associated with capacity building and self-determination. The principles of inclusion, for example, remind evaluators and community members to include rather than exclude members of the community, even though fiscal, logistic, and personality factors might suggest otherwise. The capacity building principle reminds the evaluator to provide community members with the opportunity to collect their own data, even though it might initially be faster and easier for the evaluator to collect the same information. The accountability principle guides community members to hold one another accountable. It also situates the evaluation within the context of external requirements and credible results or outcomes (see Fetterman, 2005a: p. 2).

Concepts

Key concepts guiding empowerment evaluation include critical friends, cultures of evidence, cycles of reflection and action, communities of learners, and reflective practitioners. These concepts are influenced by traditional organizational development and transformation theorists including Argyris and Schon (1978) and Senge (1994), as well as evaluators associated with organizational learning (Preskill and Torres, 1999). A critical friend is an evaluator who facilitates the process and steps of empowerment evaluation. They believe in the purpose of the program, but provide constructive feedback. They help to ensure the evaluation remains organized, rigorous, and honest.

Empowerment evaluators help cultivate a culture of evidence by asking people why they believe what they believe. Community members and program participants are asked for evidence or documentation at every stage, so that it becomes normal and expected to have data to support one's opinions and views. Cycles of reflection and action involve ongoing phases of analysis, decision making, and implementation (based on evaluation findings). It is a cyclical process. Programs are dynamic, not static, and require continual feedback as they change and evolve. Empowerment evaluation is successful when it is institutionalized and becomes a normal part of the planning and management of the program.

Empowerment evaluation is driven by a group process. It is a community of learners. The group learns from each other, serving as their own peer review group, critical friend, resource, and norming mechanism. Individual members of the group hold each other accountable concerning progress toward stated goals. Finally, empowerment evaluations help create reflective practitioners. Reflective practitioners use data to inform their decisions and actions concerning their own daily activities. This produces a self-aware and self-actualized individual who has the capacity to apply this worldview to all aspects of their life. As individuals develop and enhance their own capacity, they improve the quality of the group's exchange, deliberation, and action plans.

Steps

There are many ways in which to implement an empowerment evaluation. In fact, empowerment evaluation has accumulated a warehouse of useful tools. The three-step (Fetterman, 2001) and ten-step (Chinman et al., 2004) approaches to empowerment evaluation are the most popular tools in the collection.

Three-Step

The three-step approach includes helping a group: (1) establish their mission; (2) take stock of their current status; and (3) plan for the future. The popularity of this particular approach is in part a result of its simplicity, effectiveness, and transparency.

Mission

The group comes to a consensus concerning their mission or values. This gives them a shared vision of what is important to them and where they want to go. The empowerment evaluator facilitates this process by asking participants to generate statements that reflect their mission. These phrases are recorded on a poster sheet of paper (and may be projected on an LCD projector depending on the technology available). These

phrases are used to draft a mission statement (crafted by a member of the group and the empowerment evaluator). The draft is circulated among the group. They are asked to 'approve' it and/or suggest specific changes in wording as needed. A consensus about the mission statement helps the group think clearly about their self-assessment and plans for the future. It anchors the group in common values.

Taking Stock

After coming to a consensus about the mission, the group evaluates their efforts (within the context of a set of shared values). First, the empowerment evaluator helps members of the group generate a list of the most important activities required to accomplish organizational or programmatic goals. The empowerment evaluator gives each participant five dot stickers, and asks the participants to place them by the activities they think are the most important to accomplish programmatic and organizational goals (and thus the most important to evaluate as a group from that point on). They can put one sticker on five different activities or all five on one activity if they are concerned that activity will not get enough votes. The top 10 items with the most dots represent the results of the prioritization part of taking stock. The 10 activities represent the heart of part two of taking stock: rating.

The empowerment evaluator asks participants in the group to rate how well they are doing concerning each of the activities selected, using a 1 (low) to 10 (high) scale. The columns are averaged horizontally and vertically. Vertically, the group can see who is typically optimistic and/or pessimistic. This helps the group calibrate or evaluate the ratings and opinions of each individual member. It helps the group establish norms. Horizontally, the averages provide the group with a consolidated view of how well (or poorly) things are going. The empowerment evaluator facilitates a discussion and dialogue about the ratings, asking participants why they gave a certain activity a 3 or 7.

The dialogue about the ratings is one of the most important parts of the process. In addition to clarifying issues, evidence is used to support viewpoints and 'sacred cows' are surfaced and examined during dialogue. Moreover, the process of specifying the reason or evidence for a rating provides the group with a more efficient and focused manner of identifying what needs to be done next, during the planning for the future step of the process. Instead of generating an unwieldy list of strategies and solutions that may or may not be relevant to the issues at hand, the group can focus its energies on the specific concerns and reasons for a low rating that were raised in the dialogue or exchange.

Planning for the Future

Many evaluations conclude at the taking stock phase. However, taking stock is a baseline and a launching off point for the rest of the evaluation. After rating and discussing programmatic activities it is important to do something about the findings. It is time to plan for the future. This step involves generating goals, strategies, and credible evidence (to determine if the strategies are being implemented and if they are effective). The goals are directly related to the activities selected in the taking stock step. For example, if communication was selected, rated, and discussed, then communication (or improving communication) should be one of the goals. The strategies emerge from the taking stock discussion, as well, as noted earlier. For example, if communication received a low rating and one of the reasons was because the group never had agendas for their meetings, then preparing agendas might become a recommended strategy in the planning for the future exercise.

Many programs, projects, and evaluations fail at this stage for lack of individual and group accountability. Individuals who spoke eloquently and/or emotionally about a certain topic should be asked to volunteer to lead specific task forces to respond to identified problems or concerns. They do not have to complete the task. However, they are responsible for taking the lead in a circumscribed area (a specific goal) and reporting the status of the effort periodically at ongoing management meetings. Similarly, the group should make a commitment to reviewing the status of these new strategies as a group (and be willing to make midcourse corrections if they are not working). Conventional and innovative evaluation tools are used to monitor the strategies, including online surveys, focus groups, interviews, as well as the use of a quasi-experimental design (if appropriate). In addition, program-specific metrics are developed, using baselines, benchmarks or milestones, and goals (as deemed useful and appropriate). For example, a minority tobacco prevention program empowerment evaluation in Arkansas has established:

1. Baselines (the number of people using tobacco in their community)
2. Goals (the number of people they plan to help stop using tobacco by the end of the year)
3. Benchmarks or milestones (the number of people they expect to help stop using tobacco each month)
4. Actual performance (they record the number of people they help to stop using tobacco and compare their figures with their goals and benchmarks to determine if they are making progress or need assistance)

These metrics are used to help a community monitor program implementation efforts and enable program staff and community members to make midcourse corrections and substitute ineffective strategies for potentially more effective ones as needed. These data are also invaluable when the group conducts a second taking stock exercise (3–6 months later) to determine if they are making progress toward their desired goals and objectives. Additional metrics enable community members to compare, for example, their baseline assessments with their benchmarks or expected points of progress, as well as their goals. See also Fetterman (2003a, 2010) for the use of descriptive or ethnographic techniques.

The 10-Step

The 10-step approach is another useful tool. It is called Getting-to-Outcomes (GTO®) (Chinman et al., 2004). GTO is a method for planning, implementing, and evaluating programs in order to achieve success. GTO provides a framework of 10 accountability questions. When answered with quality it provides a pathway to help programs achieve results and demonstrate accountability (see **Table 1**).

Table 1 GTO accountability questions

1. Needs assessment	What are the needs and resources in your organization/school/community/state?
2. Goal setting	What are the goals, target population, and desired outcomes (objectives) for your school/community/state?
3. Science and best practices	How does the intervention incorporate knowledge or science and best practices in this area?
4. Collaboration; cultural competence	How does the intervention fit with other programs already being offered?
5. Capacity building	What capacities do you need to put this intervention into place with quality?
6. Planning	How will this intervention be carried out?
7. Implementation/process evaluation	How will the quality of implementation be assessed?
8. Outcome and impact evaluation	How well did the intervention work?
9. Total quality management; continuous quality improvement	How will continuous quality improvement strategies be incorporated?
10. Sustainability and institutionalization	If the intervention is (or components are) successful, how will the intervention be sustained?

These steps and guiding questions are designed to build evaluation capacity and improve the probability of program success and sustainability. There are many GTO manuals with worksheets designed to address how to answer each of the 10 questions (e.g., Chinman et al., 2004). GTO has been used in multiple domains, including substance abuse prevention, underage drinking (Imm et al., 2006), promoting positive youth development (Fischer et al., 2006), and home visiting programs (Mattox et al., 2013).

Clarifying Issues in Empowerment Evaluation

A sample of issues concerning the use of empowerment evaluation is presented below to provide additional conceptual clarity. They range from the locus of control to the audience for empowerment evaluation and are briefly discussed below.

1. *Empowerment*. People empower themselves. A common misconception about empowerment evaluation is that it empowers either individuals or groups. Empowerment evaluation cannot empower anyone. Empowerment evaluation simply provides the tools and environment conducive to empowering oneself.
2. *Objectivity and advocacy*. Empowerment evaluation is transparent, brings bias to the surface, and generates meaningful data to inform decision making. These findings are used by staff, community members, and other relevant parties to advocate for their programs or communities as data merit.
3. *Consumer focus*. Consumers (community members, program staff, and participants) are the driving force or focus in empowerment evaluation. However, evaluators and donors remain an integral part of empowerment evaluation
4. *Internal versus external evaluation*. Empowerment evaluation (internal evaluation) and traditional forms of evaluation (typically external evaluation) can be mutually reinforcing. They are not mutually exclusive. However, external evaluations should be rooted in internal concerns; otherwise, they may divert program staff, participants, and resources from the most relevant issues given the organization's stage of development.
5. *Purpose*. Empowerment evaluation's most significant contribution is to program or community development. However, it makes a strong contribution to accountability by cultivating internal accountability. This contribution remains long after an episodic and often anticipated external examination.
6. *Bias*. Empowerment evaluations are typically more critical of their own programs than external examinations (which are often influenced by their interest in returning for a follow-up or extended engagement). Empowerment evaluations provide people with a window of opportunity to address long-standing issues of dysfunction and inefficiency in their own organizations. In addition, the process is inclusive and transparent, open to critique and review, and makes it difficult to keep people from publicly 'speaking their truth.'
7. *Outcomes*. Empowerment evaluations are highly collaborative and participatory in nature. However, the bottom line remains: did you accomplish the desired results? Empowerment evaluations are conducted within the context of what people are already being held accountable for in their communities or workplaces. This makes the entire process more credible and authentic.
8. *Audience*. Empowerment evaluators believe that everyone can benefit from being more empowered. Although much of empowerment evaluation's focus has been on disenfranchised populations, empowerment evaluators assume all people can benefit from taking greater control of their lives, particularly from a positive psychological growth perspective.

Additional points providing greater conceptual clarity, as well as additional discussion about methodological specificity and outcomes, are discussed in detail in the literature (Fetterman, 2001; Fetterman and Wandersman, 2005, 2007). Christie (2003) has also revealed a unique contribution that empowerment evaluation has made to the field and how to differentiate its contribution from similar approaches (see also Fetterman, 2003b).

Conclusion

Empowerment evaluation is firmly rooted in the field of evaluation. The approach has been applied internationally, debated in refereed journals, and is the subject of longitudinal research. The first empowerment evaluation book *Empowerment Evaluation: Knowledge and Tools for Self-assessment and Accountability* (Fetterman et al., 1996) was controversial since it proposed turning evaluation on its head – allowing community and staff members to conduct their own evaluations. That book helped launch the approach, focusing on breadth and scope of

empowerment evaluation, as well as useful tools. The second empowerment evaluation book *Foundations of Empowerment Evaluation* (Fetterman, 2001) consolidated arguments and pertinent discussions in the field. It also applied the utility, feasibility, propriety, and accuracy standards (based on the Joint Committee on Standards for Educational Evaluation). The third empowerment evaluation book *Empowerment Evaluation Principles in Practice* (Fetterman and Wandersman, 2005) introduced the 10 principles guiding empowerment evaluation. The fourth book *Empowerment Evaluation: Knowledge and Tools for Self-Assessment, Evaluation Capacity Building, and Accountability* (Fetterman et al., 2014b) represents the product of over 20 years of experience, providing additional conceptual clarity and methodological specificity. Empowerment evaluation continues to be a self-assessment approach designed to help people help themselves, using evaluation to build their capacity and accomplish their goals.

Abstract

This article reviews revolutionary changes, which have occurred since 2000 regarding the creation and publication of reference books and online sources. Factors that have altered the way that such books, especially those pertaining to the social sciences, include the increased speed of composition due to word-processing technology, the downsizing of libraries as they switch from printed to electronic reference sources, and the increased pressure upon academics to publish rapidly, especially in Britain. The article also offers a concise history of social science reference works in several disciplines, beginning in the eighteenth century and ending with the present.

The Old World of Reference Publishing

Historic Overview of Reference Works

According to one informed estimate, if a copy of every important reference work known in Western history were set side by side in chronological order, some two miles of shelf space would be required for their display. Ever since Plato and Aristotle first called for the assembling of what they named 'encyclopedia' – a challenge quickly accepted by one of Plato's nephews, Speusippus (d. 339 BC) – intellectuals have tried to summarize and codify what they knew, either for general literate audiences or for specialized groups of colleagues. Of these two miles of systematized learning, those volumes that treat the social sciences would appear in only the last several hundred yards of material, in the material produced since the Enlightenment, since the social sciences in their modern form are largely products of the Enlightenment. Clearly, social science was not part of the trivium/quadrivium arrangement of classical and renaissance learning, and official academic status was accorded these fields only during the last century in most research universities.

The history of encyclopedias, handbooks, and dictionaries (designations which until at least the eighteenth century were used interchangeably) is distinguished not only by sheer quantity of printed material, but also by the quality of thinkers and writers who created and contributed to them. Pliny the Elder's *Natural History*, for instance, served as a model of organizing such material for 1700 years after its appearance in AD 77, despite an odd mixing of fact and fancy throughout its 37 books. Francis Bacon devised in 1620, a huge encyclopedia of 130 sections that was never completed, but his mode of organizing knowledge was still consulted by Diderot and later compilers 130 years later. In 1817, Samuel Taylor Coleridge also put forth an ambitious reorganizing of all human knowledge, which he interestingly titled *Encyclopædia Metropolitana*.

The urge, then, to systematize and rationalize both common and esoteric knowledge has been strongly and continuously in evidence for at least 2400 years in the West. Even in AD 551 when the love of knowledge and external conditions for its preservation reached an apparent nadir, Cassiodorus saw to it that the labors of the monastery he founded at Vivarium be dedicated principally to the preservation of worthwhile information, producing the 2-volume *Institutes of Divine and Secular Literature*. Vincent of Beauvois has long been identified as the finest encyclopedist of the Middle Ages, producing his *Speculum majus* (*The Greater Mirror*) in 1244, made up of 10 000 chapters in 80 books, an achievement that held the field for sheer scope until the eighteenth century. Alphabetical as opposed to categorically arranged encyclopedias began to appear at the turn of the first millennium, though most have followed the latter rather than the former method of organization. And the first grouping of all knowledge within a format that is recognizably modern, along alphabetical lines, was the *Grand Dictionnaire Historique* produced by Louis Moreri in 1674. The audience for such a work was already developed, for his venture went through six editions in the following 17 years, followed by still more editions in English.

Growing Availability of Reference Works

It was not always so difficult to name the leading works to which scholars or novices could turn when searching for basic information regarding the social sciences, especially if one strays beyond the confines of the English language. There was a time, of course, when dictionaries, handbooks, and encyclopedias (which in Greek means 'general education') could have been viewed as a special genre of scholarly display, with Samuel Johnson's *Dictionary* (1755), Diderot's *Encyclopedia* (1751), or Voltaire's *Philosophical Dictionary* (1764) initially setting the tone for many modern versions that followed. As noted above, for some centuries prior to the Enlightenment, the words 'dictionary' and 'encyclopedia' were used synonymously, lacking precise meaning, e.g., when Rabelais around 1534 introduced the word into French literature, in *Pantagruel*: "he has opened for me the true well and abyss of encyclopedic knowledge" (*The Complete Works of François Rabelais*, University of California Press, 1991, p. 201). Though Rabelais meant simply 'knowledge' when using the term, within only 25 years a German, Paul Scalich, had published his *Encyclopaedia*, the scope of which conformed to today's usage. Since then, of course, untold thousands of such works have appeared in every major language.

But unlike scholarly articles and books, rolling off the presses with merciless regularity, substantial reference works have until recently been rarely enough published that they eluded the standard procedure of critical appraisal brought to

bear on most nonreference works. And they are hardly the innocent, bland summaries, which the naive reader might take them to be. Each new entry into this crowded market must either claim to bring together for the first time a body of knowledge which to that point had not been assembled by quite the same rules as those which constitute the 'new' rubric, or it must offer some other, less lofty advantage, such as lower price or ease of use. All of this is currently going in the world of social science publishing, and at an unprecedented rate, mostly owing, one suspects, to the huge composing advantages supplied by personal computers.

The positive result of the new technology lies in the superabundance of suddenly available reference resources, some of which will surely define for the first time entire realms of intellectual inquiry. A less sanguine prospect, however, is the burden this torrent of innovative materials places on those who most evaluate or use them. As the range of choices widens, the provision of usable criticism becomes ever more costly, and probably less reliable.

This was not always the case, at least regarding the social sciences. A fairly limited selection of well-known reference tools were at the disposal of researchers in the late nineteenth and early twentieth centuries, which gave this growing general zone of study a tidy coherence that today is all but gone. And whereas such an orderly presentation of knowledge, then common to a given discipline or subdiscipline, might today seem either unnecessary or epistemologically indefensible, for the founders of the social sciences (*Geisteswissenschaften*) 100 years ago, the task of proving to more established disciplines that intellectual coherence indeed existed within their upstart fields became a truly vital effort at self-preservation.

Systemization of Reference Works

Within what we could now broadly call sociology, for example, systematizations appeared fairly early. This is interesting for a number of reasons, not least of which is the fact that sociology as a discipline was defined and taught (particularly in the U.S.) some time before its sister disciplines within the social sciences. It often played the role of avant-garde as this new way of carving up the academic world began rearranging disciplinary boundaries. While many of today's practitioners are familiar, at least with the titles, of the *Encyclopedia of the Social Sciences* and *The International Encyclopedia of the Social Sciences*, or Robert E.L. Faris's (Ed.) *Handbook of Modern Sociology* (1964) or Neil Smelser's (Ed.) *Handbook of Sociology* (1988), most are not aware of this genre's substantial tradition, especially as produced in Europe. It is now commonly supposed that Faris' was the first handbook of American sociology to be published, since it was widely distributed at the time and was fortunate in appearing just as sociology became a 'growth industry' on campuses worldwide. But even some reviewers at the time knew better, e.g., Joseph Gittler's opening line in his review: "With the plethora of new handbooks, reviews, and compendia in sociology, one wonders whether there is a need for yet another one" (Gittler, 1965: p. 335). But it must have seemed like much less of a 'milestone in the field of sociology' – as the publisher had characterized the *Handbook* through its mailed advertisements to American Sociological Association (ASA) members – if one considers the substance of the reviews it received. The book was probably taken as a handy cribbing device for grad students and young instructors, glanced at perfunctorily, then parked on the shelf with similar volumes which Rand McNally had become good at marketing.

As Gittler was hinting, the history of sophisticated handbooks that sought to introduce audiences to new trends of analysis is in fact long and distinguished, though it is quite true that only few of them were in English. Carl von Rotteck and Carl Welcker edited the *Staats-Lexikon oder Encyclopädie der Staatswissenschaften* (1834–43), the oldest I have found, adding up to 15 volumes at 800 pages each. (Even though the social sciences hardly existed at that time, formally speaking, the subject matter in the *Encyclopädie*, as well as the other sources named below, included much of what we would now recognize as such.) In 1852 and 1853, Charles Coquelin oversaw production of the *Dictionaire de L'economie Politique* in 2 volumes (1858 pages). Meanwhile in Italy, Gerolamo Boccardo brought out *Dizionario della economnia politica e del commercio: Cosi teorico come practico* (1857) in 4 volumes and 2800 pages, an equally lavish item.

The predecessor to Weber's famous *Grundriss der Sozialökonomik* was Gustav Schoenberg's *Handbuch der politischen oekonomie* (1882–85) in 3 volumes. Surely the most important of these early handbooks was edited by Conrad et al., *Handwörterbuch der Staatswissenschaften* (1895), an enormous work in 7 volumes and about 6000 pages. Supplements were added in 1895 and 1897 of 2000 pages, and later editions (1898 and 1909–11) included two versions of Weber's famous *Agrarverhältnisse im Altertum* (first translated in 1976 as *The Agrarian Sociology of Ancient Civilizations*), the initial version 27 pages long, the second 136 pages. Ludwig Elster, part of Conrad's team, published a shorter version of the monumental work in only 2 volumes (1898), merely 2100 pages in length. The French were not idle, with Léon Say and Joseph Chailley's *Nouveau Dictionnaire d'Economie Politique* (1891/1892), amounting to 2-fat volumes of 2800 pages, and a supplement in 1900 of 271 more. Finally, the famous Robert Harry Inglis Palgrave edited *Dictionary of Political Economy* (1894, 1900–1901), which in its last version came to 3 volumes and 2500 pages. This was soon followed in 1897 by William D.P. Bliss' *Encyclopedia of Social Reform*, 1 volume of 1439 pages (1908). What all this shows is that the notion of social science compendia has been around quite a while, and that most of the nineteenth-century European models were enormous publishing achievements. With the new century, ambitions and costs both shrank considerably.

The New World of Reference Publishing

Recent Changes in Reference Publishing

In the dozen years since the first version of this article was written, the world of reference volumes has undergone a revolution more profound than any in living memory, and perhaps more radical in its ultimate effect than any since Diderot released his 'long-delayed *Prospectus*' for the *Encyclopédie* in 1750 (Furbank, 1992: p. 74). Diderot, of course, did not invent the idea of a scholars' encyclopedia, but he improved existing models to such an extent that his, in print to this day, is regarded as 'the first.' The sea-change that recently overtook reference work production is of an even greater magnitude than that registered by the appearance of Diderot's great work – so

great, in fact, that the Era of the Reference Book as known to scholars of the past 200 years may be at its end. That *The International Encyclopedia of the Social and Behavioral Sciences*, 2nd edition, was initially to be marketed exclusively in an electronic edition, whereas its first version was also available as a set of books, hints at some of these changes, although it is certainly a pertinent observation that this decision was rescinded and the current work has been made available in both hard copy and electronic formats.

Several disparate forces conjoined to alter the nature of social science reference works such that the very idea of 'reference' has inalterably shifted from one format, accepted for centuries, to another that is truly new. Prior to the global adoption of Wikipedia, Google Scholar, Google Books, and their many offspring, reference works were typically compiled over many years, the creative province of expert scholars and scientists, offered mainly in printed form as books, very costly to produce, and rarely revised. Cheap word-processing and its ultimate gift to writers, the 'copy and paste' function, has made it easy to borrow creatively from a world of source material, including even plagiarizing oneself for disparate occasions. Naturally, these technical changes have sped up and simplified production by a very large factor.

The Shift toward Electronic Libraries

Though the beloved 11th edition of the *Encyclopædia Britannica* (1910) did not include an article about its own origins and greatness, the same cannot be said for its replacement, the self-reflexive Wikipedia. As the entry for Wikipedia says about itself: it was "launched on January 15, 2001 … [its] departure from the expert-driven style of encyclopedia building and the presence of a large body of unacademic content received extensive attention in print media." Meanwhile, Google Books, launched in October 2004 amidst great ambivalence and anxiety from publishers, authors, and scholars, had by March 2012 scanned over 20 million books into its globalized database. What began with obliging help from only a handful of major research libraries in the Anglophone world soon grew into a surprising flood of participating institutions. This development also contributed to the wholesale destruction of printed materials in libraries pressed, as they always are, for space, since once a book was scanned by Google Books, it was assumed to be forever available in that form. The fact scanning a book is not always done perfectly (omitted pages, blurred images, lack of color reproduction, etc.), or that not everyone has access to printers should they need a paper copy, has not stopped libraries from ridding themselves of their printed books at an astonishing rate, including, of course, their reference materials. In fact, discarding 'old' reference materials became a priority among avant-garde officials at large libraries, ever hungry for more shelf space. Only a Don Quixote fighting for the printed form could object to this apparently 'rational' welcoming of digitization and few have appeared to rescue 'old' books from landfills across the country.

Digitization of Content and Labor

While Wikipedia developed its early articles by importing into its site the nonpareil 11th edition of the *Britannica*, Google Books originated no new content, instead scanning millions of volumes at scores of worksites into a form that allows readers selective, and often very limited, access to pages within scanned volumes, and to search for terms within each book. Despite legal battles in the U.S. and abroad (especially in France), the 'googlization' of everything in print proceeds apace. Books still under copyright, however, cannot be read or searched in their entirety, which causes endless frustrations for scholars looking for material sequestered from their sight. This becomes particularly distressing when university libraries discard their printed volumes or fail to buy them to begin with, relying on 'someone else' to supply needed materials to their researchers. Thus, the ancient 'problem of the commons' has surfaced in a new form peculiar to academic libraries, and especially as it pertains to reference materials.

Yet aside from technical changes of speed and access introduced through the Internet, other alterations of reference materials occurred as libraries worldwide cut their labor costs by firing or 'repurposing' reference librarians *en masse*. These trained professionals, often women and stereotypically maternal and catholic in their approach to helping all library patrons, had been the foundation of public and university libraries for at least 125 years, ever since communities and campuses collectively decided that any town worth its name must have a library staffed by helpful, literate librarians. That career as such is almost gone. In its place, at even the finest university libraries, one discovers that 'the reference desk' is either absent entirely in lieu of self-service computers by the dozen, or is staffed by a transient young person without special knowledge who simply 'googles' any question put to them. So, instead of a mature librarian with proper educational credentials finding answers to questions by means of large, expensive, and trusted reference volumes, well thumbed and well known to their users, a young, inexpensive (even unpaid) amateur refers to computerized reference sources just as any citizen might who has access to their own computer.

The Shift toward Quanity

Abundance of Reference Materials

Moreover, and perhaps just as important over the last dozen years, academics and their publishers (most noticeably in the United Kingdom) have fallen under increasing pressure to 'produce' published works on an unforgiving timetable. The conventional 'factory speed-up' in manufacturing has spread to the 'academic factory.' This form of 'labor discipline' as applied to professors originated during the regime of Margaret Thatcher, who disliked the pampered 'chattering classes,' and wished to put them on a work schedule not unlike those applied to ordinary white-collar laborers in other 'industries.' British publishers responded to the resulting scholars' need to write ever more, and ever more swiftly, by issuing 'print on demand' monographs at extraordinary prices, hoping to sell most of them to libraries in North America, a far larger market than the United Kingdom's. Along with this manufactured pressure for scholars to publish rapidly, and for publishers to meet their sales goals in an ever-shrinking market for scholarly monographs, a number of well-known British publishers (followed hesitantly by their American counterparts) began to

issue dozens of handbooks, companions, encyclopedias, and dictionaries of social science material. This concatenation of forces produced an avalanche of reference materials the like of which had never been seen in libraries prior to about 2000.

It would require dozens of pages even to list all the handbooks, companions, dictionaries, encyclopedias, and guides, which have been 'cranked out' since 2000. When offered in printed form, their high prices and physical heft have consigned them almost exclusively to libraries rather than individuals. Few are offered in affordable paperback format. No one knows how often they are now consulted, given that the students and scholars educated over the last 20 years or so have become almost entirely reliant upon online sources of ready information. In today's campus phraseology, the notion of 'trudging' to the 'brick and mortar' library, 'hauling down' a 'fat tome,' which claimed when published to offer authoritative overviews of a given topic, is as alien to today's students as learning Latin or Greek. Since many of these reference volumes to not circulate, the articles of interest must be photocopied, another ancient technology happily superseded by ubiquitous printers connected to billions of personal computers all over the planet. Since there are no longer any clearly superior or inclusive reference sources in the social sciences as there once were (e.g., *The Encyclopedia of the Social Sciences*, 1933; *The International Encyclopedia of the Social Sciences*, 1968), it becomes difficult to identify those of particular merit for several reasons. The standard production format for today's reference volumes usually prohibits long-term investment of time or money, since revisions of those that sell well must occur rapidly. Editors at publishing companies which specialize in reference volumes typically seek academic advice when identifying a marketable topic. They then select a fairly senior or visible specialist in that area, pay them a very modest amount when gauged by the time they will likely invest in the project, and then leave it up to the volume editor(s) to find subeditors or authors for particular areas that need to be covered.

Influence on Authorship

Authors of the actual articles, which usually vary from 500 to 1500 words in a dictionary-like volume, all the way to 10 000 words or more for chapters in a handbook, are often paid little or nothing, it being assumed that they (being often younger scholars) need to publish rapidly, so will eagerly agree to work for free merely to get into print. This means, of course, that the most qualified scholars, those who have been working the longest on a given topic – unless, of course, it is brand new, or seems to be – are not as often found in such handbooks or guides as one might wish they were. The obvious trade-off lies between rapidly written pieces by junior scholars and researchers versus the work of seasoned experts whose presence in such volumes would require more time and money than the publisher is willing to invest. One such volume before me now, published in 2012 and aimed at the U.S. market, features two editors – Associate Professor (UK) and Professor (UK) – and authors from the following ranks: Postdoctoral Fellow (Australia), Assistant Professor (US), Postdoctoral Fellow (UK), Assistant Professor (US), Associate Professor (UK), Professor (UK), Senior Lecturer (UK), Lecturer (UK), doctoral student (Sri Lanka), private scholar (UK), and so on. Most of these writers are young, and wonderful as their work may well be, they are not recognized authorities on the topic in question. The standard response of reviewers when and if they evaluate such volumes is to say that 'the chapters/entries are uneven in quality,' as one would expect. And because such publications, rightly or wrongly, are regarded by administrators and other professional arbiters as not being peer-reviewed, they carry much less scholarly or reputational weight than more conventional publications. All of this notwithstanding, the flood of such books (in printed and electronic forms) shows no signs of retreating.

It may be worthwhile to mention a few of the many hundred recently published reference sources, if for no other reason than to indicate the vast topical range they now cover. This broad landscape of coverage is as much due it seems to the business needs of publishers as to any actual or perceived need on the part of working researchers. Unlike with expensive monographs or other special volumes, library acquisitions of such volumes are seldom the result of faculty input; in fact, few faculties are aware what reference volumes their libraries acquires since their presumed market is the student body rather than professors. This means that libraries purchase such works either under 'blanket order plans' or randomly, as one or another subject bibliographer so chooses. The purchase prices are so high and the production costs so low that publishers can profit from relatively few sales, particularly given print-on-demand technology.

Main Publishers of Reference Works for the Social Sciences

The main publishers today of reference works in the social sciences (and other areas of learning) are Ashgate (Surrey, UK and Vermont), Cambridge University Press (Cambridge, UK and New York City), Elsevier (Amsterdam and Oxford), Oxford University Press (Oxford, UK and New York City), Routledge (London and New York City), Sage (London) and Sage (California), and Wiley-Blackwell (Oxford, UK and Massachusetts). Among these several and more, hundreds of volumes have appeared in the last half-dozen years.

For example, Sage has recently published 'handbooks' on the following topics: qualitative research (2011), grounded theory (2010), international higher education (2012), mix methods in social and behavioral research (2010), social psychology (2007), interview research (2012), action research (2007), social network analysis (2011), qualitative research (2005), organizational research methods (2009), persuasion (2012), intercultural competence (2009), quantitative methodology for the social sciences (2004), leadership (2011), organizational institutionalism (2008), social cognition (2012), interpersonal communication (2011), innovation in social research methods (2011), qualitative methods in health research (2010), punishment and society (2012), political communication (2012), sociology of religion (2007), and organization studies (2006), to name only a few from their complete list.

Oxford and Cambridge have been creating handbooks and 'companions' for decades, long before Ashgate or Sage existed as reference publishers. Their imprimatur continues to lend to

their books a scholarly legitimacy, which may have outlived its actuality, given the ferocious competition among publishers for this market.

Oxford's famous handbook series, which varies somewhat in tone from Sage's, includes treatments of political institutions (2008), comparative politics (2009), political economy (2008), international relations (2010), causation (2012), positive psychology (2011), law and politics (2010), public policy (2008), political methodology (2010), political psychology (2003), Internet studies (2013), leadership (2012), intergroup conflict (2012), sociology and organization studies (2010), corporate social responsibility (2009), stress, health, and coping (2010), organization theory (2005), history of consumption (2012), organizational psychology (2012; 2 volumes), gender and politics (2013), urban politics (2012), traumatic stress disorders (2012), and American bureaucracy (2012), again, the tip of a large iceberg.

Cambridge University Press reference volumes have become indispensable in certain areas of research. The 'companions' series has become virtually a small world unto themselves, e.g., on science fiction, Kant, American novelists, atheism, utopian literature, gothic fiction, Jesus, Bob Dylan, Wittgenstein, and so on. Most are more firmly anchored in the humanities than the social sciences, although the companions to Tocqueville, Marx, Durkheim, Weber, Foucault, or Levi-Strauss each speak unambiguously to sociological interests. Cambridge also publishes handbooks, for instance, on 'the study of mental health' (2009).

Less august British companies have also leapt into the reference book trade with some success. Ashgate has invested heavily in its 'research companion' series, covering avant-garde topics like critical geopolitics (2013), war (2012), political violence (2012), queer theory 2009), globalization of health (2012), heritage and identity (2008), modern warfare (2010), multiculturalism (2010), cosmopolitanism (2011), democratization in Europe (2013), and biosocial theories of crime (2011), a few among many others. It has obviously worked hard to distance itself from the output of its rivals, whose participation in this market has been much longer.

The same can be said for Routledge, although an older company overall, has only recently begun to generate large and costly reference works whereas in its past, serious monographs were its forte. The market for such books having shrunk very considerably since neither scholars nor libraries are able any longer to spend large sums on single volumes, Routledge like so many of its peers has shifted to reference works. Its 'companion' series, imitating Cambridge, covers postmodernism (2011), critical theory (2006), religion (2009), philosophy of psychology (2011), social and political philosophy (2012), digital consumption (2013), identity and consumption (2012), social theory (2009), postcolonial studies (2007), feminism and postfeminism (2002), organizational change (2011), bioethics (2013), multicultural education (2009), postmodernism (2007), decolonization (2000), video game studies (2013), and emotional and behavioral difficulties (2012), to list a few from a large set. Routledge also offers 'handbooks,' e.g., on contemporary social and political theory (2011), identity studies (2011), cosmopolitan studies (2012), cultural sociology (2010), and climate change and society (2010), among others.

Imitation among publishers is obviously a factor in the production of these volumes as one can see from multiple entries under the most pressing current concerns: cosmopolitanism, social media, climate change, postcolonialism, and so on. It seems that eventually all reference materials will become electronic, and the production of long, heavy, expensive printed volumes created by many hands will cease. Even large academic libraries have begun to resist acquiring them as a matter of course, opting instead for a subscription to electronic versions, forgoing the purchase of its printed companion. Some libraries in computer-linked systems are sharing costly reference volumes through interlibrary loan, a practice which for decades was inconceivable since such materials by definition did not circulate. All this, like so much else in the world of scholarly publishing, is changing too rapidly for even seasoned researchers to absorb. Audiophiles are returning in significant numbers to vinyl reproductions of sound, and one wonders if a 'return to the printed book' might not also be on the horizon after the novelty of digitized knowledge sources wears thin.

Reference Works by Discipline

Sociology

Although in the space allotted here it is impossible to offer even a succinct history of social science reference books, some sense of how they evolved over the last century or so might be conveyed simply by means of mentioning some titles which seemed to define a given discipline at a particular moment in its development. I will begin with my own field whose history is more familiar to me than the other disciplines.

Despite its senior status as a university discipline of independent identity relative to most of the other social sciences, reference works have not been as numerous for sociology as one might therefore expect. Thomas Nixon Carver's *Sociology and Social Progress: A Handbook for Students of Sociology* (Sumner, 1907: 810 pp.) was remarkable for its earliness. Yet the first real encyclopedic effort in English came only in 1992 under Edward Borgatta's editorship (Macmillan: 4 volumes), a full century after academic departments bearing the discipline's name appeared in several midwestern universities. (Two previous efforts, one edited by the noted scholar Michael Mann, did not live up to their titles as 'encyclopedias' proper.) Other useful compendia include Smelser and Swedberg's *The Handbook of Economic Sociology* (1994) and Frank Magill's *International Encyclopedia of Sociology* (1995: 2 volumes).

The first handbook expressly designed for sociology was Alfred Vierkandt's *Handwörterbuch der Soziologie* (1931), a mere 690 pages long, followed in 1956 by Werner Ziegenfuss' *Handbuch der Soziologie,* at double the length. And in 1962 Rene König edited the famous *Handbuch der Empirischen Sozialforschung* in 2 volumes of 2000 pages. In the United States one could begin with *An Introduction to Sociology* edited by Jerome Davis and H.E. Barnes (1927, 1931), a 900-page collabora by seven authors. *Trends in American Sociology* followed in 1929, edited by George Lundberg, Read Bain, and Nels Anderson, with substantial chapters on the history of sociology, theory, social psychology, culture, rural sociology, urban sociology, educational sociology, social work, applied sociology, and

methods. In 1937 Prentice-Hall sold *Man and Society* for $3.75, a 787-page work edited by Emerson Schmidt that tried to introduce students to all the social sciences simultaneously, covering everything from human values to income distribution to social psychology (Herbert Blumer's memorable chapter). The Gurvitch-Moore volume, *Twentieth Century Sociology*, published just following the war (1945), seemed to have widespread influence, despite its execrable typos and layout. Its most distinctive feature, in addition to chapters on all the subfields of sociology at the time, was a second section of 250 pages that dealt with sociology in France, the United States, Britain, Germany, Latin America, Italy, Spain, Russia, Poland, Czechoslovakia, Rumania, and Yugoslavia. This should have inspired later handbooks, and may account for the volume's popularity, since a distinctly ecumenical flavor swept the academy worldwide following World War II. Its authors – Burgess, Parsons, H.P. Becker, Sorokin, Maclver, Znaniecki, Gurvitch, Roscoe Pound, Merton, Wach, Levi-Strauss, Faris, Albert Salomon, Bastide, and so on – comprise a list of distinguished scholars that has not been matched since in a collaborative volume. The first recognizably 'modern' compendium was Joseph Gittler's *Review of Sociology* (1957), with chapters by recognized authors on the topics that soon became the staples of introductory textbooks. (Georges Gurvitch edited *Traité de sociologie* in 1960, 2 volumes and 1000 pages, which seemed to have little impact in the United States.) And finally, Parsons himself had a go with his *American Sociology* (1968), with chapters by many scholars now in the twilight of their careers but who then were the bedrock of the mainstream, as it were.

One could say many things along these lines about the Smelser *Handbook*, which, given its size and unique position within sociology at present, deserves more than passing attention. This is especially so regarding the 'theories' that are put forth in the opening chapters as constituting 'the' new streams. For instance, neither Walter Wallace nor Jeffrey Alexander, the chapters' authors, wishes to consider postmodernism as a fact of existential and scholarly life, and therefore each throws himself or herself into a strange time warp. Peterson had characterized Faris' introduction to his earlier compendium as 'blindly benign' (Peterson, 1965: p. 254), which seems perfectly correct, even when rereading Faris today. One could say something similar about the theoretical terrain that is gingerly walked over in opening chapters of the Smelser *Handbook*. A range of old beliefs, now diminished by criticism from philosophers and literary critics – some of whom, incidentally, number among our most influential 'social' theorists – are trotted out as if nothing substantial had occurred to Western culture since 1964. It is as if the 'self' about which Parsons wrote with such conviction is still out there doing what selves have 'always' done. The same could be said about the precritical notion of 'science' and 'rationality' that figures in both chapters, but especially in Alexander's, as if definitions of rational action and societal rationality are not now in themselves enormously contentious topics. Such limitations begin to indicate the intellectual boundaries of compendia of this sort, even those written by top scholars, for the adventurousness that might pervade a monograph composed by the same authors is diminished when they turn their hands to 'general' statements. Since reference sources, by common consent, are supposed to offer a summary of 'established knowledge' in a specific field or subfield, their authors typically draw back from the perimeters of discovery and innovation. Therefore, such works almost always lag behind the leading edges of thinking and offer their users a snapshot of what was confidently held to be true a dozen or more years before they are published. And with the ever-increasing rate of change in global intellectual culture, this poses a problem, particularly for printed reference sources, which may be met only via constantly updated electronic versions.

Comparison of Smelser's *Handbook*, the most recent entry into the genre, with earlier versions must remain fairly rough. Its predecessors employed other sorts of authors, aimed at different audiences (those not yet effectively lobotomized by videocretinization), and seem to have been composed in an atmosphere of genuine wonder and hopeful discovery regarding what social scientific study might yield for intellectuals and for the social order that supported them. This kind of childlike hope decomposed after the Gurvitch–Moore volume in 1945 and was replaced by a somewhat defensive, stuffy scientism in later compendia that reflected sociology's struggle to survive McCarthyism on one hand, literary criticism on the other. But such books, while high on scientific rhetoric, seemed correspondingly low on political self-examination and savvy, while also revealing a foreshortened understanding of the philosophical problems necessarily part of sociological study. Still, it is uplifting to read these older books because their authors were usually straightforward and unpretentious. They tended to avoid enormous claims for the discipline, and offered up its fruits with a direct and unembattled character that nowadays is harder to find. It is probably no accident that after years of sociology bashing at the highest levels of government, both here and in Europe, the field should have put out a summary package for broad consumption in hopes of regaining lost ground, both within the cloister and beyond its high walls. We shall see if it succeeds as part of the long process of recertifying the discipline for a public which has been told repeatedly that nothing good can come of thinking about social reality in the way 'we' do.

Dictionaries for sociology began with Constantine Panunzio's pamphlet, *A Student's Dictionary of Sociological Terms* (California, 1937), continuing with Henry Fairchild's *Dictionary of Sociology* (1944). Only in the late 1960s were a number of competing volumes added to this small shelf of sociological reference books, including those of Geoffrey Mitchell (1968, 1979), George and Achilles Theodorson (1969), and Thomas Hoult (1969). With Raymond Boudon and François Bourricaud's *Critical Dictionary of Sociology* (1989), celebrated scholars from Europe entered the field for the first time, followed in the 1990s with new dictionaries by David Jary (1991), Nicholas Abercrombie (1994), Gordon Marshall (1994, 1998), and Allan Johnson (1995), the former three being well-known British scholars. American sociologists have not of late contributed substantially to this genre.

Anthropology

Of all the social sciences, anthropology has been to date the least well served in terms of general reference books. This seems odd given the nineteenth century's penchant for vast

compilations of quasi-anthropological data, e.g., Frazer's *Golden Bough* or Herbert Spencer's *Descriptive Sociology* (in fact comparative anthropology) in 12 volumes. The earliest dictionary of sociology that I have found has now become a standard, Charles Winick's *Dictionary of Anthropology* (1956), with several later editions. *Anthropology A to Z* (1963), edited by Gerhard Heberer, Carleton Coon et al., was based on an earlier German compilation of several hands. A recent trend among publishers, to name reference books after their firm, is typified in *The Macmillan Dictionary of Anthropology* (1986) edited by Seymour-Smith. The implication of this general practice – that a source's value to the user is more or less guaranteed by virtue of a firm's prestige – is not necessarily realized in practice. The most recent entry is Barfield's *Dictionary of Anthropology* (1997).

The discipline came into its own so far as references sources go when Honigmann et al. produced the 1300-page *Handbook of Social and Cultural Anthropology* (1973) at a period when the social sciences reached a zenith of appeal among college undergraduates in the U.S. Two misnamed volumes are Hunter and Whitten's *Encyclopedia of Anthropology* (1976) and Barnard and Spencer's *Encyclopedia of Social and Cultural Anthropology* (1996), both books of modest size. An interesting twist appeared with Bock's *Handbook of Psychological Anthropology* (1994), an instance, ever more common, of a reference book seemingly anticipating an intellectual or disciplinary trend before it gains acceptance at the institutional level. Such a rubric might well surprise both psychologists and anthropologists, relatively few of whom typically relate their two fields in any intimate way.

Cognitive Sciences and Related Fields

As soon as it became apparent in the 1970s to policy makers, governmental budget specialists, and academics that improvements in psychopathic or sociopathic conditions could be more cheaply and quickly realized through the use of drugs and related somatic measures – as opposed to 'talking cures' or other socially based interventions – those fields that stress the linkage between individual physiology and the social order experienced a sudden renaissance. What seemed a neo-Darwinian rage for simplification overtook large zones of inquiry within the social and behavioral sciences. This has become so much the case during the last decade that physiological reductionism often seems the order of the day, nearly extinguishing the behavioral component in explanations for an ever-broadening range of ailments, from alcoholism to schizophrenia to general criminality. Given this intellectual environment, it is hardly surprising that a range of new reference books appeared which positioned themselves along a continuum of biobehavioral explanation of social action, from crude sociobiological reductionism to subtle neurological analysis of brain function and behavior. Much of this new wave of work stirs up controversy because of its real or imagined political consequences, most famously exemplified by the raucous reception given Herrnstein and Murray's *The Bell Curve* (1994), both in the ordinary as well as the academic press.

Among many such books, which have recently been published, several might be mentioned for their innovative qualities. Michael Gazzaniga edited *Handbook of Cognitive Neuroscience* (1984), complemented by Dunlop and Fetzer's *Glossary of Cognitive Science* (1993), brought to even grander fruition in Wilson and Keil's *The MIT Encyclopedia of the Cognitive Sciences* (1999). Not unrelatedly are Wyer and Srull's *Handbook of Social Cognition* (1984, 1994) and Van Hasselt and Hersen's *Handbook of Social Development* (1992). More traditional, and connected with a field the roots of which go back at least to Saussure's posthumous masterpiece, *Course in General Linguistics* (1916), is Florian Coulmas's *The Handbook of Sociolinguistics* (1997), and what amounts conceptually to its complementary volume, Morton Gernsbacher's *Handbook of Psycholinguistics* (1994). These interestingly hybrid fields will undoubtedly grow in the new century, and it seems now that a biosocial focus will stimulate at least as much theorizing and research as did the more purely sociopolitical analyses during the preceding half-century.

Economics

Unlike some of the newcomers mentioned above, economics (or 'political-economy' as it was first known) has a long history relative to other social sciences, dating at least to 1776 and the publication of Smith's *Wealth of Nations*. Reference sources therefore abound. Before economics became an academic area, many guides to financial matters existed, of course, e.g., *The Handbook of Trade and Commerce, or, A concise dictionary of the terms and principles of trade, commerce, manufactures, commercial and common law, etc., with tables of money, weights, and measures*, published in London in 1840. We also know from sources like Marx's *Theories of Surplus Value*, his 3-volume anthology of annotated excerpts from the history of economic theory, that the literature on economic matters was by the 1850s quite well developed. Reference works, however, did not apparently surface until somewhat later. Palgrave's *Dictionary of Political Economy* (1894) is perhaps the most famous, and John Joseph Lalor's *Cyclopedia of Political Science, Political Economy, and the Political History of the United States: By the Best American and European Writers* (1881–84) is another early example. So was Frank Bower's *A Dictionary of Economic Terms for the Use of Newspaper Readers and Students* (1905), kept in print until 1951 under subsequent editors.

More obviously pertinent to the discipline as it now exists was Herwith Price's *Economic Dictionary*, 2 volumes (1926–29), published in Berlin, as well as John Todd's *The Mechanism of Exchange: A Handbook of Economics* (3rd edition, 1927) (which became *The Science of Prices* in a 4th edition (935) before reverting to its original title in its 5th). Frank Bower's brief *Dictionary of Economic Terms* reached its 10th edition in 1936, while Horton's *Dictionary of Modern Economics* appeared in 1948. Beginning in the early 1950s, the number and variety of dictionaries and handbooks concerning economics exploded, keeping pace with undergraduate enrollments at large public universities in the U.S. and elsewhere. Sloan and Zurcher's went through five editions between 1951 and 1970, while J.L. Hanson's reached its 6th edition in 1986, having been in print for 21 years. The latest dictionaries of economics include those by John Black (Oxford, 1997) and Bannock et al. (Wiley, 1998). On a larger scale, encyclopedias of economics began to appear relatively late, with the Guilford *Encyclopedia of Economics* in 1973/74, the *McGraw-Hill Encyclopedia of Economics* in 1982 and 1994 (2nd edition), and *The Fortune*

Encyclopedia of Economics in 1993. O'Hara has reverted in his choice of title to an earlier time, perhaps for political as much as intellectual reasons, with *Encyclopedia of Political Economy* in 2 volumes (1999). Another new entry is K. Liou's *Handbook of Economic Development* (1998), which broadens the discipline's terrain by including the global dimension.

Political Science

One of the earliest general reference works in this area is *Political Dictionary: Forming a work of universal reference, both constitutional and legal; and embracing the terms of civil administration, of political economy and social relations, and of all the more important statistical departments of finance and commerce* (London, 1845–46) in 2 volumes. It is instructive that those fields, which in the mid-nineteenth century seemed closely enough linked, empirically and practically, to be treated within a single work, have since the mid-twentieth century been torn asunder into mutually incompatible and incomprehensible camps of specialists, who have little to say to one another except at ceremonial occasions. This situation is not necessarily an advance in social knowledge. The 14-volume *American Annual Cyclopaedia and Register of Important Events: Embracing Political, Civil, Military, and Social Affairs* (New York, 1862–75) does not take in political science per se, though would surely have uses to the historian of the discipline. Already mentioned, John Lalor's 1882 *Cyclopedia of Political Science* […] is among the first to use the term in the modern sense. Another amalgamated volume that typifies an era unafraid to mix disciplines was William Bliss's *Encyclopedia of Social Reform: Including political economy, political science, sociology and statistics* (1897), some 1439 pages in length.

Dictionaries and lexicons of political science are as numerous as encyclopedias or handbooks are scarce. William Connolly's *Terms of Political Discourse* (1974) and Maurice Cranston's *Glossary of Political Terms* (1966) were produced by scholars who subsequently became well known for other work. Joseph Dunner's *Dictionary of Political Science* (1964), Jack Plano's *Political Science Dictionary* (1973), and Roger Scruton's *A Dictionary of Political Thought* (1982) are several among a score of similar works, which, as in neighboring fields, have been increasing in number, length, and complexity during the last decade. Works of larger scope, in terms of length as well as conceptual breadth, include David Miller's *The Blackwell Encyclopedia of Political Thought* (1987, 1991), Hawkesworth and Kogan's *Encyclopedia of Government and Politics* (1992: 2 volumes), and Goodin and Klingemann's *A New Handbook of Political Science* (1996).

Psychology

Just as the number of undergraduate majors in psychology typically overwhelms those of all the other social sciences, with ratios often running five or six to one or higher, so with reference books attached to this enormous field. The most distinguished early survey was surely William James's *Principles of Psychology* (1890: 2 volumes), in print continuously ever since, in full and abridged versions. Clark Murray's *Handbook of Psychology* (1885, 1888), James Sully's *Teacher's Handbook of Psychology* (1886, 1909: 5th edition), and the *Handbook of Psychology* (1889–91: 2 volumes) by William James's equally famous contemporary, James Mark Baldwin, were each substantial compilations, and helped give psychology a head-start toward producing a unified view of the social world vis a vis its sister disciplines. More eclectic viewpoints were expressed in Geoffrey Rhodes's *The Mind at Work: A Handbook of Applied Psychology* (1914) (with help from the noted sociologist, L.L. Bernard) and in Leander Keyser's *A Handbook of Christian Psychology* (1928: 2nd edition). By 1931, however, the field had become thoroughly professionalized, as exemplified by Anderson, Buhler, and A. Freud et al., *A Handbook of Child Psychology* (1933: 2nd edition), and its companion volumes in the Clark University series, H. Banister et al., *A Handbook of General Experimental Psychology* (1934: 1125 pp.) as well as Allee, Allport, et al., *A Handbook of Social Psychology* (1935: 1195 pp.). Somewhat less innovative were W.B. Pillsbury's *Handbook of General Psychology* (1942), Kimball Young's *Handbook of Social Psychology* (1946), or Lindner and Selger's *Handbook of Correctional Psychology* (1947). Specialization within the discipline had already reached such a pitch that in 1950 Norman Munn offered *Handbook of Psychological Research on the Rat* (first published in 1933 as *A Introduction to Animal Psychology*).

The 1950s were a boom period for psychology reference works of the larger scale, reflecting the discipline's ever-widening influence in Western societies, with at least six more 'handbooks' entering the market. In more recent times innovation has once again become commonplace, with books like M. Gazzaniga's *Handbook of Psychobiology* (1975), Raaig, Veldhoven, et al., *Handbook of Economic Psychology* (1988), and Crawford and Krebs's *Sociobiology and Psychology* (1987), which recently became the *Handbook of Evolutionary Psychology* (1998). The last volume intimates a strong connection currently being forged between researchers with refreshed enthusiasm for neoevolutionary doctrines on the one hand, and sociobiological explanations for behavior on the other. This general tendency – in some ways a repudiation of earlier causal models for social action and psychological states – has been given substantial impetus by the genome project and related studies that attempt to link physiology with behavior in an unmediated fashion.

Encyclopedias have also been a more regular feature of psychology's disciplinary life than in other fields. Early efforts included McKean's *The Encyclopedia of Psychology: A series of graphic descriptions of human characteristics* (Brussels, 1928) and Philip Harriman et al., *Encyclopedia of Psychology* (1946). The 1970s exploded with new versions varying substantially in size and scope. Robert Goldenson's *Encyclopedia of Human Behavior: Psychology, Psychiatry, and Mental Health* (1970: 2 volumes) brought together supplementary fields, just preceding the herculean effort by Benjamin Wolman et al. (300 editors and 1500 authors), *International Encyclopedia of Psychiatry, Psychology, Psychoanalysis and Neurology* took up 12 initial volumes (1977) plus a supplement (1983) and surely set a new standard for comprehensiveness of these allied research areas. Wolman also edited a 1-volume *Encyclopedia of Psychiatry, Psychology, and Psychoanalysis* in 1996. Another half-dozen encyclopedias of psychology proper appeared during the late 1970s and 1980s that of Raymond Corsini's running to 4 volumes (Wiley, 1984) and Frank Magill's reference book production team brought out the *Survey of Social Science: Psychology Series* (1993) in

6 volumes, grandly renamed the *International Encyclopedia of Psychology* when reissued and reset in 1996. (Magill and his specialty editors have produced like volumes for all the social sciences in his *Survey* series.)

Ever since James Mark Baldwin published *Dictionary of Philosophyy and Psychology* (1901–05: 3 volumes; new edition, 1928), there has never been a shortage of dictionaries for the discipline. I have identified 35 in English alone, some of them of continuing interest simply for the peculiarity of their design, at least by today's standards, e.g., William Taylor's *Taylor's Dictionary of Bio-Psychology, Genetics, and Various Branches of Applied Psychology* (1925: 148 pp.), or Vergilius Ferm's *A Dictionary of Pastoral Psychology* (1955). Of the more standard fare – a score or more appear in most standard bibliographies – many were compiled by the same scholars who oversaw production of the encyclopedias named above, with the most lavish entries all appearing during the 1990s.

Conclusion

Were Moreri and his contemporary compilers alive today, they would probably be astonished at the level of continuing interest in reference sources. Informed academic reference librarians and professional bibliographers now claim that we are living in a golden era of reference materials, especially if one uses sheer quantity of output as the vital measure of the gold standard. One director of acquisitions wrote of "So Many Choices, So Little Money" regarding new reference books (Wilkinson, 1997), and the editor of *The Book Review* of *The Library Journal* recently analyzed 'reference for a new age' with particular attention to the mesh of electronic and printed materials suddenly dominating publishers' catalogs (Hoffert, 1996). A third expert notes that flashy graphics and other user-friendly alterations have attracted many first-time users to reference materials who before would have shunned their perceived complexity (Mantell, 1997). Even a cursory look at the current availability of dictionaries, handbooks, or encyclopedias in the social sciences indicates that in some fields, for which before 1990 virtually no reference books (let alone CD-ROMs) were available, now have at their disposal a half-dozen fresh entries in the genre. And even at considerable cost, they are being bought by research libraries almost as a matter of course, just as the electronic forms have begun to encroach on printed versions. The latter may continue to exist into the upcoming century, but will probably be relegated to the status of secondary resources, subordinate to the newer formats. Or they might persist as specialized bodies of information for ever-smaller audiences. Overall, it is fair to say that the reference materials 'business' is thriving as never before, especially when measured by library acquisition budgets aimed in its direction, and the ultimate effect this outpouring may have on the way social science is conceived and used remains difficult to predict.

That said, however, no one seems to be arguing that the latest entries into the reference book market are supplanting in quality of information or breadth of coverage some of the old standards. *The Encyclopedia of the Social Sciences* from the early 1930s will never be rendered entirely obsolete simply because so many of its contributors have themselves become the subjects of articles in later works. What was true in 1910 of the 11th edition of the *Encyclopaedia Britannica*, still the nonpareil standard of reference works in English, is similarly the case for a range of earlier works. When authors close to the origin of a given field of research accepted invitations by reference publishers to write about their own scholarly innovations (e.g., Werner Sombart on 'Capitalism' in the *ESS*, Benedetto Croce's article on 'Aesthetics' or Edmund Husserl's on 'Phenomenology,' both in the 14th edition of the *Britannica*), later authors have been obliged to accept such statements as first-order expert testaments, beginning their reformulations from there. Surely some of this is going on today, for instance, in newer fields like 'cognitive neuroscience,' 'psycholinguistics,' 'psychobiology,' or 'economic psychology,' and a century hence these may well be accepted as foundational statements. (Certainly, all of these 'reformulations' are accorded extensive treatment in the current work!) But for the time being, it is hard to distinguish the ephemeral from the more or less permanent when evaluating the raft of reference works that have appeared during the last decade or so.

End of Life Choices

Frances Norwood, George Washington University, Washington, DC, USA

© 2015 Elsevier Ltd. All rights reserved.

As advancements in medicine, pharmaceuticals, and technology at the end of life have proliferated, particularly in Western industrialized nations around the world, the range of choices for people at the end of life has not. Nature and culture strike a delicate balance at the end of life today. Choice is not simple, but instead follows a highly structured, cultural script. Ultimately, death is biological and in one sense of that word, inevitable. Importantly, however, death is also a cultural event, and 'choices' are those options culturally scripted and publically mediated that allow people to die within and outside of culturally appropriate ways of dying in places around the world. In the Foucauldian sense, choice is an illusion. But even that is not absolute, as individuals creatively push against and transform even the most sacred traditions around the end of life. This article is about end-of-life choices in contemporary societies, and predominantly Western industrialized countries, and the role of culture in shaping those choices.

It is ironic that as advancements in medicine, pharmaceuticals, and technology at the end of life have proliferated, particularly in Western industrialized countries around the world, choices for people at the end of life have not. Ultimately, death is biological and in one sense of that word, inevitable. Clearly, the body is an organism that is affected by natural processes that determine life, health, disease, decline, and death. Importantly, however, death is also a cultural event, and 'choices' are those options culturally scripted and publically mediated that allow people to die within and outside of socially appropriate ways of dying in places around the world. Nature and culture strike a delicate balance at the end of life today. Choice about the end of life is never a simple choice, but instead may follow a highly structured, cultural script about how to die.

According to philosopher Michel Foucault (1972, 1991), choice is somewhat of an illusion and discourses are scripts that emerge in societies – cultural forms that shape the way we think, feel, and act. Discourses are not simply spoken exchanges, but limit what can be spoken, what is constituted as taboo, what is held in collective conscience, what is reconstituted from the past, and who in society has access (Foucault, 1972: 115; Foucault, 1991: 58–60). Dominant discourses – like those of modern-day medicine – limit the ability we have to make independently derived decisions and choices in cultural practice. As Foucault states, "in every society the production of discourse is at once controlled, selected, organised and redistributed according to a certain number of procedures, whose role is to avert its power and its dangers, to cope with chance events, [and] to evade its ponderous, awesome materiality" (Foucault, 1972: 216). Add to that the limitations of biology, and the decline of the human body and 'end-of-life choices' become a phrase not well suited to describe the end of life today.

End-of-life discourses among scholars, policy makers, health care providers, families, and the media are highly mediated by concepts of nature and culture, where players at the end of life – physicians, patients, families, medical associations, law, the media, and powerful industries such as pharmaceutical, hospital, and insurance industries – invoke 'nature' and 'culture' as needed to further their oftentimes competing agendas. Yet, neither of these concept categories or the scripts behind them are absolute as individuals creatively push against and transform even the most sacred traditions around end of life. From euthanasia in the Netherlands to the overtreatment of patients at the end of life in the US to the inequalities of access in India, individuals, culture, and nature strike a delicate and complicated balance at the end of life. This article is not a comprehensive, legal history of end-of-life choices in places in all parts of the world, but rather focuses on the interplay between nature and culture at the end of life, highlighting the role of culture in shaping prevalent end-of-life choices in a few contemporary societies.

Nature and Culture in End-of-Life Choices

In social science, death is often at the debated intersection between nature and culture, where 'nature' is often represented by some combination of natural process, materials from God, or biological fact and is opposed to 'culture,' alternately defined as human manipulation of nature (a cultural intervention) or as what it is not (not pristine, not 'natural'). Scholars who have examined this dichotomy closely have suggested that both nature and culture are permeated by aspects of the other to such an extent that the opposition is no longer a useful tool (Nader, 1996; Strathern, 1992; Yanagisako and Delaney, 1995). Marilyn Strathern in her book *After Nature* (1992), for example, takes on postmodern notions of nature and culture, which suggest that both are cultural constructions where nature is consumed by a sea of pluralistic, fragmentary, and ever-emerging process of cultural construction. Nature vanishes in postmodern thought, replaced and subsumed by culture. Strathern argues that nature and culture are neither in competition (dualistic), nor consumed one by the other, but instead coexist one within the other. She writes,

> [c]ulture and nature may be connected together as each operates in a similar way according to laws of its own; at the same time, each is also connected to a whole other range of phenomena which differentiate them – the activities of human beings, for instance by contrast with the physical properties of the universe. This second connection makes the partial nature of the analogy obvious. It presupposes that one thing differs from another insofar as it belongs to or is part of something else.
>
> Strathern, 1992: 73

So what is 'after nature' is at the same time connected to it, but in modern-day practice nature has come to be trivialized, a product of the consumer's choice. Strathern writes, "[i]ts image may be borrowed here and there, slapped on to products as a new dimension, a kind of marketed contextualization that reinvents human responsibility as a matter of discriminating between products" (Strathern, 1992: 197).

In the debates around death and dying, these varying conceptions of nature and culture permeate – nature and culture as discrete dichotomous entities; nature as cultural construction; and nature and culture as derivatives of the other. Is death the place where culture ends and nature reasserts itself or is the biology of death and dying inextricably reliant on culture for meaning? The difficulty of pinpointing even the changing biology of death, as demonstrated by different conceptions and receptions of brain death and organ transplantation for instance, demonstrates the inextricable connections that nature and culture share (Hogle, 1999; Lock, 2002; Scheper-Hughes, 2004, 2005).

Nature, Culture, and Brain Death in Japan

It is often assumed that death is merely a biological or 'natural' event. Anthropologist Margaret Lock takes issue with that in her ethnography *Twice Dead* (2002), where she finds that concepts of brain death do not fit well with pervading cultural understandings of life and death in Japan. She points out that until the advent of life-prolonging technologies, such as cardiopulmonary respiration (CPR) and the artificial respirator, and advances in medicine around organ and tissue transplantation, did it become necessary to reassign death from failure of the heart and lungs to 'brain death.' She writes, "[i]t was essential that the new death be a diagnosable event and that it be timed to allow the removal of organs while they remained 'fresh' and reasonably well oxygenated. No longer based on the commonsense notion of the end of life – a failure of heart and lungs – the new death is determined by the condition of the brain alone, even though the body clearly remains biologically alive, albeit with mechanical assistance" (Lock, 2002: 78).

Reassignment of death from the heart and lungs to the brain was necessary in places around the world in order to facilitate organ and tissue removal and reuse. The new demarcation of death also served to avert legal complications and to address public fears. Lock writes, "[t]he very existence of ventilator-dependent patients raised two concerns: first, the fear of being counted dead before one's time and over hastily designated an organ donor; second, the fear of being kept alive too long, as a 'vegetable,' with severe, irreversible brain damage, but not technically brain-dead" (Lock, 2002: 78).

The rollout of the new death received different cultural reactions in places around the world. In Germany, for instance, the legacy of the Holocaust has manifested in a general reluctance toward organ procurement (Hogle, 1999) and in some nonindustrialized countries evidence is showing that the commodification of body parts is a burden not shared equally (Scheper-Hughes, 2004). In Japan, organ transplantation and brain death continue to be viewed as 'unnatural.' Cultural notions of tradition and modernity, Japan and the Western 'other,' religion and medicine, individual and society, and distrust of the medical establishment come into play in Japan. Lock writes, "[d]eath in Japan remains above all a social event; the family is in control, and death with dignity requires family participation… The concept of brain death is seen by many as a clumsy creation of technological medicine, devised to hasten the end of life [and] because the concept of 'person' is not usually lodged exclusively in the brain, locating death in the brain causes discomfort" (Lock, 2002: 369).

Denying Death: Cultural Constructions at the End of Life

Many social scientists have focused on the cultural aspects of death and dying, either arguing against the reification of biology and science or to delineate the powerful role of culture at the end of life. A common theme that has shaped how social scientists and cultural historians view the end of life is the focus on modernity, or industrialized cultures, as death denying. In *Western Attitudes toward Death* (1974), historian Philippe Ariès argues that attitudes toward death in Western societies (predominantly Europe and the US) have changed over time and across cultures. He identifies death in the Middle Ages as a 'tame death' in which the dying person assembles his or her family, friends, neighbors, doctors, and priests bedside, orchestrating the ritual and its protocol, and ceremoniously making his or her final exit. Death during this time was viewed as a fact of life and the types of end-of-life choices that people of this time had were largely to die quickly due to injury or disease and in the relative comfort of home and family. Death in the Middle Ages was inevitable. In Ariès words, "in death man encountered one of the great laws of the species, and he had no thought of escaping it or glorifying it" (Arìes, 1974: 28). By the twelfth century, this resignation to the 'collective destiny' of dying shifted to a more individualistic approach to death. The dying person became more concerned with his or her own death, viewing it as a type of judgment day. This shift toward individualism, he argues, has remained throughout the present time.

By the eighteenth century, death became a more dramatized event, and the focus shifted from the dying person to the grieving survivors who now saw death as a disruption of their own economic and social lives. During this time, the family was given more power over the event of death; mourning became much more expressive; and a 'cult of memory' was created to mark the event for those most affected by it: the survivors (Arìes, 1974: 66–67). Today, according to Ariès and a number of other researchers, modern death has undergone a transformation marked by a type of denial of death (Arìes, 1974; Becker, 1973; Giddens, 1991; Glaser and Strauss, 1968; Gorer, 1955; Walter, 1994). Ariès explains, "death, so omnipresent in the past that it was familiar, would be effaced, would disappear … it would become shameful and forbidden" (Arìes, 1974: 85). Death moved out of the home to be cleaned, sterilized, and sequestered in institutions of medicine, moved from the private, family-dominated space of home into hospitals where death could largely be erased under layers of disease-focused, body-compartmentalizing, and technology-driven medical intervention.

In *The Denial of Death* (1973), anthropologist Ernest Becker disagrees with the timing of denial, arguing that denial and fear of death is universal to human beings of all cultures and times. The world is a terrifying place, he says, marked by creation and destruction; life, violence, and the inevitability of death. Human beings naturally react with anxiety or fear, which gives rise to repression of that anxiety or denial of death. Denial of death is not enough to deal with the terror of life, however, so society creates a 'hero system,' designed to help us transcend death in this life by showing that we are part of something worthwhile (Becker, 1973: xiii).

Sociologist Anthony Giddens, in contrast, argues that denial of death is not something universal to all cultures across time,

but something new. He links denial to the onset of modernity (1991). Giddens argues that death, sickness, and other 'non-normal' types of human experience (e.g., criminality or mental illness) are hidden or sequestered from daily social life. The 'sequestration of experience' is a process intrinsic to modernity in which nonnormal experience is physically removed from ordinary social life, housed in institutions of control, such as prisons, asylums, or hospitals, and then socially reconstituted via a modern predisposition toward self-reflexivity and the resulting internalization of society's rules, values, and norms (Giddens, 1991: 1–34, 156–162). Sequestration allows a separation "from 'original' nature and from a variety of experiences bearing on existential questions and dilemmas" and from "direct contact with events and situations which link the individual lifespan to broad issues of morality and finitude" (Giddens, 1991: 8). In this sense, sickness, dying, and death in modernity are found to be outside of the social system, sequestered and hidden from view, resulting in existential disconnect. He writes, "personal meaninglessness – the feeling that life has nothing worthwhile to offer – becomes a fundamental psychic problem in circumstances of late modernity" (Giddens, 1991: 9).

A growing number of social scientists are challenging this view of modern society as death denying. Both Giddens and sociologist Clive Seale question Ariès' view of the 'tame' death as a contrast to modern-day denial, citing evidence from Elias which suggests that death in the Middle Ages was not as tame as Ariès shows it to be (Giddens, 1991: 161; Seale, 1998: 52–54). Seale also questions theories put forth by Becker and Ariès, which rely on the presence of fear as the explanation for denial of death. Seale argues that the evidence does not necessarily support the premise that fear was alleviated by religion prior to modern-day society or that medical science offers alleviation from fear today (Seale, 1998: 76).

In *Constructing Death* (1998), Seale suggests that those who view modern society as death denying are confounding psychological denial with sociological denial of death. He argues that at the psychological level modern-day societies are seldom death denying. He writes,

> [d]eath is in fact actively managed in modernity and thus can be understood as the result of a characteristically modern, full square and unflinching facing of death at the personal level. No doubt there are individuals who are helped to suppress their personal fears by the fact that dying people are less visible, but there are many others who engage in a rather practical acceptance of the realities of death. Not least, the host of 'experts' in health care who are, after all, also a part of 'society', are very often remarkably accepting of the facts of death, supported by the routinisation of care that modern bureaucratic organisations provide.
> Seale, 1998: 54

Death is 'hidden away' in modern, industrialized societies, but not because of a psychological denial of death, but because the dead have little power to disrupt social bonds in modern society. Seale explains,

> [t]he continuing social existence of the dead, intervening in the affairs of the living, as ghosts, spirits or ancestors, is a good indicator of the degree to which death is disruptive of social order. Ghosts can be understood, largely, as reifications of the unfinished business of people who die when still socially engaged. In general, the society of the dead can be understood as socially controlling the moral life of the living… [T]he dead, in modern societies, are relatively powerless.
> Seale, 1998: 52

Seale argues that the aged and the dying are sequestered from everyday life, devalued, segregated, and controlled, but while death in modern times may be suppressed from immediate social physicality and awareness, everyday life is at the same time permeated by social, symbolic, and embodied enactments of the 'renewal of life against death' (Seale, 1998: 70).

Anyone flipping through prime-time television with the proliferation of violent crime dramas and supernatural walking-dead entertainment might agree with Seale, questioning whether we truly are a collection of death-denying societies. Anthropologist Geoffrey Gorer (1955) makes a compelling argument that takes into account the proliferation of mediated death in modern-day societies. He suggests that as Western societies rejected some of the rituals around death, at the same time they became more open to sexuality, and ultimately, he argues, death replaced sex as the new taboo in many places. While violent, nonnatural deaths took on an almost pornographic tone in mediated forms, 'natural' or ordinary, everyday death from illness, disease, and old age and the rituals and mourning practices associated with those were denied (Gorer, 1955). Several authors since then have looked at the rise in graphic, mediated forms of death around the world (Bogard, 2008; Foltyn, 2008; Gibson, 2007; Hanusch, 2008), including sociologist William Bogard who suggests that our current preoccupation with unnatural, graphic, and violent death marks a shift from social control via the corpse to social control via modulation of hybrid life forms (Bogard, 2008: 191). The corpse, Bogard argues, once pivotal in Foucault's (1973) concept of biopower, has been replaced. New biopower relies on control over life and choices at the end of life as new global discourses aimed at "technologies for generating organs, growing hybrid bodies, and creating life *in vitro*" now dominate (Bogard, 2008: 188).

Medicalizing End-of-Life Choices: Hospital Death and Its Options

In the backdrop of these changing cultural constructions of death and dying, discourses of medical science have emerged to largely overtake the end of life, making death and end-of-life choices increasingly medical concerns (Porter, 2001; Starr, 1982). By the twentieth century, physicians and medicine replaced chaplains and religion at the bedside of the sick and the dying. Key advances in medicine, such as the advent of antisepsis techniques in surgery and the ability to maintain oxygen flow via the artificial ventilator, allowed many people to live longer lives, but that also meant that suffering was prolonged (Lock, 2002: 57–75; Lynn, 2004: 4–31). A hundred years ago, the average life expectancy was 47 years in the US and most people died at home from infections or accidents after experiencing at most hours or weeks of decline before death. Today, life expectancy and living with chronic illness

have both increased dramatically. In 2000, US life expectancy averaged around 75 years and people were most likely to die in the hospital with an average of 2 years of chronic conditions and decline (Lynn, 2004: 1–10). Death and dying, once the domain of the priest, family, and home has largely become medicalized, overtaken by the physician, the hospital, and medical interventions with powerful industries and interests – medical, hospital, insurance, and pharmaceutical – vying for the declining body and pervading end-of-life choices.

Research suggests that in many cultures, certainly not all, the preference is to die at home (Kaufman, 2005; McWhinney et al., 1995; Townsend et al., 1990). Yet, in most Western industrial nations many continue to die in the hospital. In the US in 2005, for example, approximately 45% of Americans died in hospitals, 22% in nursing homes, and only 25% died at home where most say they would prefer to be when they die (Brumley, 2002; CDC, 2005; Tang, 2003). In a recent study comparing death in six European countries, the majority of people died in hospitals ranging from 63% in Sweden and Wales, 59% in Scotland, 58% in England, and 52% in Belgium (Cohen et al., 2008). The Netherlands, known for its more progressive policies at the end of life and one of the lowest rates of hospital deaths, stands out from the rest reporting only 34% hospital deaths (Cohen et al., 2008). The Dutch Central Bureau for Statistics reports that in the Netherlands more than one-fourth of persons each year die in their own home and one-fifth die in residential or nursing home care (CBS, 2004).

Hospital-Mediated Dying: A Typical Case

Jack Carter is an 84-year-old patient with congestive heart failure taken to the intensive care unit (ICU) after a heart attack and by day 10 in the ICU he is not improving. His cardiologist has been treating him for the last 8 years and knows Mr Carter and his advance care wishes well. Mr Carter would take CPR and ventilator support if he has a reversible medical problem, but not if his condition could not improve. As anthropologist, Sharon Kaufman, writes, Mr Carter had "reached a crossroads on the heroic intervention pathway, and now he is stuck there."

An angiogram has been ordered to investigate the extent of the artery damage around the heart even though the contrast dye used could also cause kidney failure and the cardiologist saw it as a last ditch, and unlikely, attempt to help him live longer. Mr Carter was unsure, asking his long-time cardiologist, "what would you do?" to which his physician answered, "I'm not eighty-four. I don't know what I would do …" The nurse on duty also thought the angiogram was not the best choice, explaining that many patients like Mr Carter come in for a 'heart tune-up' and it usually takes several hospitalizations before they are ready to face death. Mr Carter is alert and animated and tells Kaufman that he has weighed the risks and is ready to go forward with the angiogram. Later, he tells the chaplain something different, fearing that he might die from the procedure. The day before the procedure, Mr Carter's blood pressure drops and soon after his cardiologist performs electric shock to stop an irregular heartbeat. It does not work and Mr Carter's heart stops beating entirely. Kaufman describes what follows: "[t]he medical team performs CPR in an attempt to resuscitate him. For nearly two hours they do chest compressions, apply electric shock, and give blood pressure medications intravenously, hoping to restore his heartbeat and blood pressure. 'He wanted aggressive treatment,' the cardiologist explains afterward." Mr Carter, 84 years of age, dies after 10 days in the ICU.

Kaufman argues that this case falls between what some would consider an inhumane death – dying after a prolonged ICU stay following the violence of CPR – and a death according to the patient's wishes – his wish to explore life-saving treatment until it was clear that sustaining life was no longer possible. She attributes Mr. Carter's problematic death to the heroic medical pathway that promotes aggressive treatment in the face of unlikely positive results and on the lack of clear guidance offered by the cardiologist. When the patient showed doubt about continuing on the heroic pathway, the doctor failed to answer his question, or discuss it further, instead putting the responsibility for deciding about death on to his patient who clearly did not have the information or time to process whether continued treatment was the best choice for him.

Sharon Kaufman, 2005. And a Time to Die: How American Hospitals Shape the End of Life. Scribner Publishers, New York, pp. 161–166.

Medical anthropologist Sharon Kaufman (2005) studied hospital death in the US, and her findings echo others who have examined hospital-dominated dying. She suggests that American medicine has attempted to stave off death with the most sophisticated and expensive treatments and technologies. Kaufman points out that as many as one-fourth of all hospitalized patients are treated in an ICU of a hospital before they die and when they enter the hospital system they enter a system that due to a complex set of circumstances – including incentives for overtreatment by specialists and the ever prevalent threat of legal action against health-care practitioners in the US – pushes life-saving treatments even when none of the participants (hospital staff, patients, nor families) view that as the best choice (Kaufman, 2005: 319). The result is a way of dying that medicalizes the end of life, alienates all involved, and results in overly aggressive interventions and treatment and, ultimately, a lack of real choices for people as they die. Studies from around the Western industrialized world demonstrate that even over the last decade, there has been a general failure of hospital medicine to change and aggressive and often futile treatments continue to pervade care for the dying even up to the time of death.

Advance Directives

Kaufman points out that one of the most prevalent 'choices' made at the end of life in the hospital is around code status, or the choice of whether or not to receive resuscitation or ventilation in the event of heart or lung failure. Advance directives, or living wills, are preferences that patients can put in writing to detail what medical actions should and should not be taken to maintain their life in the event of a medical emergency in which they would otherwise not be able to communicate their wishes. CPR is performed in the United States on anyone who does not have a written order, or advance directive, stating his or her code status. This order is called a Do Not Resuscitate order and is one of several advanced care directives that patients near the end of life can make prior to or during a hospitalization to attempt to influence the course of their treatment while in the hospital. Emergency CPR typically entails insertion of a breathing tube, chest compressions, and electronic shocks to the heart. On frail bodies near the end of life, this default procedure can be traumatic for all involved and can include breaking ribs, damaging windpipes, and postponing what could have been

a more peaceful death (Kaufman, 2005: 48–49). Ventilators are used to maintain lung functions when a patient cannot do so on his or her own. Both CPR and use of ventilators are two prevalent emergency interventions routinely used at the end of life that have great consequences on how people die, and thus are an important part of any advance directive.

Advance directives usually come in two forms: (1) various health instructions in the event of a medical emergency and (2) designation of a durable power of attorney or someone who can serve as a health proxy in the event that they are not able to advocate their end-of-life preferences for themselves. Precipitated by high-profile cases of persons left partially alive in persistent vegetative states around the world, advance directives emerged often as a patient-led response to overtreatment at the end of life and in the context of public discussions about what constitutes 'good' or 'bad' forms of dying (Brown, 2003; Emanuel and Emanuel, 1998; Hirai et al., 2006; Ishihara et al., 2008; Norwood, 2006b; Seale and Geest, 2004; Van der Geest, 2004).

In the US, for example, advance directives arose as a patient-led response to the case of Karen Quinlan in 1975 and Nancy Cruzan in 1983, both young women kept alive for many years in a persistent vegetative state. The patient's rights movement has been strong in the US and ultimately led to the Patient Self-Determination Act of 1990, which among other things recognizes the right of individuals to refuse or accept medical treatment (Brown, 2003; Norwood, 2009: 94–95). Many nations in Europe also have some variation of living wills or legislation regarding patient's rights to refuse treatment, including Austria, Belgium, Finland, Hungary, the Netherlands, Spain, Switzerland, and the United Kingdom. Bulgaria, Greece, Italy, Norway, Serbia, and Turkey do not regulate living wills and/or they are not legally binding in these countries (Brown, 2003). France, Germany, and Slovakia have policies that partially recognize either refusal of treatment or advance directives (Brauer et al., 2008).

Advance directives and how they are employed also vary quite a bit among subcultures. Many African-Americans in the US, for example, have a troubled history with the medical community following the public exposure of the Tuskegee Syphilis Study between 1932 and 1972 in which poor African-American sharecroppers from Alabama were allowed to die of syphilis even after penicillin had been identified as a cure (Kenny, 1972). More recently, the story of Henrietta Lacks was exposed, highlighting the exploitation of a poor, African-American family for medical gain (Skloot, 2010). Henrietta Lacks was an African-American woman who in the early 1950s was treated for and subsequently died of cancer at Johns Hopkins University Hospital. Physicians treating her at Hopkins took Lacks' cells, without her or her family's knowledge, which at the time was common practice. Using Lacks' cells, scientists were able for the first time to replicate an 'immortal' line of human cells grown in culture, paving the way for medical experiments previously impossible on live human subjects and resulting in a number of very profitable industries that included development of the polio vaccine and advances in the treatment of cancer, *in vitro* fertilization, cloning, and gene mapping to name only a few. Meanwhile, members of her family were only recently told of how the cells of Lacks live on, contributing to medical science but no longer owned by the woman or the family who live in poverty and without access to health care (Skloot, 2010). These and other significant historical events affect the rates at which African-Americans in the US, for example, use advance directives and have trust that clinicians will help them to receive equitable treatment at the end of life (Perkins et al., 2002).

The problems with advance directives are many. In the US, for example, too few persons think to establish advance directives prior to an emergency and clinicians too often are not having effective communications with high-risk patients and their families prior to or during an emergency. For the few with advance directives, many of these are not effectively communicated in the heat of a medical emergency. Rarely do patients with advance directives actually bring the written directive with them to the emergency department and without the availability of shared electronic health records in many places in the US the directive goes unseen. In the absence of a written advance directive, family members present with the patient are called on to recall the person's wishes, but conflicting opinions from family members, perceptions and feelings of guilt around being the one to end their loved ones life, or lack of previous communication prior to the emergency event can derail a person's end-of-life preferences. In some cases where written directives are available, clinicians will fail to heed the directive for any number of reasons including conflicting family preferences, doubts about the validity of the directive, misinterpreting the directive, conflicting hospital policy, or simply that clinician's preferences to treat (Brown, 2003; Ishihara et al., 2008; Perkins, 2007; Teno et al., 1997).

Ultimately, advance directives are problematic because as they are currently used, they represent a single point in a decision-making process that is very fluid and, ideally, must occur over time. In a qualitative study with persons dying in the Netherlands, for example, it was found in practice that people make and change their end-of-life wishes frequently. The fluid nature of advance planning in practice manifested as a 'line in the sand,' where dying individuals would say, 'I do not want to go on if I cannot do my art anymore' or 'I will want euthanasia once they remove my other leg,' but invariably as that line in the sand approached, many incorporated their new limitation only to draw another line in the sand for another day (Norwood, 2007, 2009: 75–76). In addition to shifting preferences, it is difficult to detail and plan for the various scenarios that might occur at the end of life, thus life-saving treatment may be desired in one scenario, but not in the next.

There is no quick fix for the problems with advance directives, but they are a step in the right direction. The next step to make advance directives more effective would include supporting on-going conversations that occur among patients, family members, and their clinicians regarding advance care planning and end-of-life preferences; these conversations must be periodically documented in writing in electronic medical record systems that can be readily updated and available in an emergency situation, and policy must exist both at the governmental and health system levels that facilitate the use of patient's preferences at the end of life.

Refusal of Treatment

Patients' rights legislation has emerged in places around the world to detail rights in terms of access to health care. In some places, this also includes language related to a patient's rights to refuse life-sustaining treatments (Erbay et al., 2013; Ryan and Callaghan, 2010; Saks, 2010). In addition to refusal of emergency medical treatment, such as CPR or artificial ventilation, refusal of life-sustaining treatment can also take the form of refusal of food and hydration or a treatment or procedure, such as chemotherapy, that might prolong life. Rights to refuse treatment vary quite a bit from hospital policy, to state policy, to individual preferences and once someone is on life-sustaining supports it may be difficult for families to have supports removed, which makes the decision of refusal prior to the use of artificial supports an important choice to make. In the United Kingdom where end-of-life choices frequently make headlines, for example, they passed the Mental Capacity Act of 2005, which partially allows patients to refuse treatments under limited conditions, but does not allow refusal of food, water, warmth, or hygiene by advance directive (Brauer et al., 2008: 97). In Serbia, on the other hand, the Health Care Act of 2005 allows the patient to "forgo any kind of medical treatment even that of life-saving or life-sustaining" as long as they do so in written form (Brauer et al., 2008: 76).

Medical Behaviors That Potentially Shorten Life

End of life today rarely occurs as a completely intervention-free process, thus the majority of end-of-life choices are typically medical ones. For this reason, the term medical behaviors that potentially shorten life (MBPSL) has emerged to encompass a number of medical practices that contribute to the shortening of life in response to the medicalization of death and dying. There are a number of types of MBPSL including withholding and withdrawal of support (WH/WD), euthanasia and assisted dying (or assisted suicide), terminal or palliative sedation, and life-terminating acts without an explicit request (LAWER) by the patient.

Withholding and Withdrawing Support

Withholding of life-sustaining supports, sometimes referred to as passive euthanasia, includes such medical practices as withholding artificial nutrition and hydration; withholding emergency life resuscitation, such as CPR or ventilation; and withholding life-sustaining treatments or medications, such as supplemental oxygen or antibiotics. It is typically delineated from withdrawing life-sustaining supports, which often involves an additional legal step to have someone actively removed from life-sustaining supports. Withdrawal from supports typically includes such practices as removing someone from a ventilator, nutrition, or any number of other life-sustaining supports, medications, or practices (Smedira et al., 1990).

Much of the public debate around WH/WD emerged as a reaction, again, to the high-profile cases of persons being kept partially alive in persistent vegetative states around the world. In the US, for instance, there was the case of 21-year-old Karen Ann Quinlan in 1976. After a night of drinking and drug use, Karen Quinlan collapsed into a coma at a roadside bar and for almost a year after, her family fought for the right to withdraw her from life-sustaining treatment. The family eventually won their case and Quinlan died 9 years after being disconnected from a respirator (Dowbiggin, 2005: 121–122). In 1989, the Nancy Cruzan case was heard by the US Supreme Court, which ruled that the Constitution supports a patient's right to refuse treatment if there is 'clear and convincing evidence' of the refusal. More recently, the Terri Schiavo case made headlines from 1998 to 2005. Schiavo was just 26 years old when she suffered irreversible brain damage due to complications from an 'iced tea diet' and years of damage from bulimia. She lay in a persistent vegetative state for a year before her husband petitioned for the right to remove her feeding tube. What ensued was an almost 7-year battle between her husband, her parents (who opposed withdrawing life support), the Florida legal system, and eventually the US Supreme Court. Fueled by the media, the Schiavo case tapped into deep-seated concepts of who has the right to decide (parents, husband, or state) and what constitutes life. After several attempts at state and federal legislation to block Schiavo's husband from withdrawing support, the courts determined that Terri Schiavo's wishes prior to her illness were to not continue life-prolonging measures and in March 2005 her feeding tube was removed. She died 13 days later (NNDB, 2008). More recently in India, the Supreme Court ruled in favor of WH/WD under certain circumstances after hearing the case of Aruna Shanbaug, a young woman kept alive for over 30 years on a ventilator (Goel et al., forthcoming).

Withholding and Withdrawing Support in India

In 1973, Aruna Shanbaug, a nurse in one of the leading teaching hospitals in Mumbai was raped and strangled by a hospital custodian whose advances she had spurned, leaving her brain-dead and in a persistent vegetative state. For more than 30 years, Shanbaug, shunned by her family, has been kept alive on a ventilator taken care of by former coworkers at the hospital where she worked. In March 2011, in response to a petition by a journalist on Shanbaug's behalf, India's Supreme Court ruled that Shanbaug should live, while at the same time stating that passive euthanasia – the WH/WD – be permissible in certain cases based on merit. Following the decision, it is no longer illegal to remove supports for persons who are brain-dead or in the case of some persistently vegetative patients with the knowledge and intention of ending their life.

This case sparked a new debate in India on just what kind of end-of-life options physicians and families want available. It also raises important moral and ethical conflicts regarding all types of euthanasia, active and passive, and the maintenance of life in patients whose life span has been prolonged at the cost of their quality of life without adding real hope of recovery.

In August 2011, the Indian Medical Association in association with researchers from the University College of Medical Sciences assembled a team of Indian and international physicians, policy makers, and end-of-life experts to discuss and develop policy recommendations. The group deliberated on issues related to passive euthanasia, the economics of WH/WD, the related economics of keeping vegetative patients alive using invasive technology, legal issues in physician-assisted death, and the preparedness of Indian society for advance directives. While most issues still remain in discussion, it is noteworthy that India has taken up these issues and demonstrates how important it is for societies to work out health policy in relation to their own individual cultural contexts.

With special thanks to Ashish Goel, Assistant Professor in Medicine, University College of Medical Sciences and the Indian Medical Association (Goel et al., forthcoming).

Looking at some of the rates for WH/WD shows how much these practices vary country to country. In a 2001 study of MBPSL across Europe, for instance, the EURELD study revealed that as a percentage of all deaths, WH/WD was the highest in Switzerland (41%) and the lowest in Italy (6%), with the Netherlands (30%), Belgium (27%), Denmark (23%), and Sweden (22%) somewhere in the middle (Griffiths et al., 2008: 490). Clearly, WH/WD is intricately tied to the cultural history of a place and the pervading religious or cultural views toward the end of life that vary among and between nations and their subcultures over time (Devictor and Latour, 2011; Khater et al., 2011; Smedira et al., 1990; Vogel, 2014).

Euthanasia and Assisted Dying (or Assisted Suicide)

Euthanasia and assisted dying, or assisted suicide (depending on what side of the debate the author falls), are two of the most controversial MBPSL that occur today. Euthanasia and assisted dying have existed at least as far back as we have oral history accounts and, according to anecdotal accounts, continue in medical practice today even in places where they are not legally regulated, including in the United States and places across Europe (Emanuel et al., 2000; Heide et al., 2003; Magnusson, 2004; Meier et al., 1998; Morita et al., 2002). Only recently, however, have these practices begun to fall under the realm of law.

Euthanasia (terminating a person's life at that person's explicit request typically for reasons of incurable illness) and assisted dying (providing a person with the means to terminate his or her own life typically for reasons of incurable illness) occur legally in only a few places. The Netherlands has the longest standing legal practice (defined as both legal precedence and transparency of practice) of euthanasia and assisted suicide, legalizing these practices by court decision in 1984 and by law in 2002. Today, euthanasia is legally practiced in the Netherlands (since 1984), Belgium (since 2002), and Luxembourg (since 2009). Assisted dying or assisted suicide is legally practiced in Switzerland (since 1937), the Netherlands (since 1984), Belgium (since 2002), Luxembourg (since 2009), and in the United States in Oregon (since 1997), Washington (since 2008), Montana (since 2009), and Vermont (since 2013). Most recently, the right to assisted dying was upheld by a Second District Court in New Mexico (2014) (Steck et al., 2013). The Netherlands is not the first country in the modern era to legalize euthanasia by law (Australia legalized euthanasia for a brief period in 1995), but it is the first country to legally practice euthanasia and, with nearly 30 years of legal practice, it is the country most often held as the model for or against euthanasia policies in other countries (Cohen et al., 2013; Goldstein, 2008; Heide et al., 2003; SCBI, 2002; Scherer and Simon, 1999).

While euthanasia and assisted dying have been widely debated and researched around the world (Bittel et al., 2002; Cohen et al., 2013; Davis et al., 1993; Downie, 2004; Foley and Hendin, 2002; Førde et al., 1997; Hendry et al., 2013; Plattner, 1996; Quill and Battin, 2004; Televantos et al., 2013), very few comprehensive, ethnographic studies of what euthanasia and assisted dying are in practice exist (Norwood, 2009; Pool, 2000; The, 1997). Using ethnographic research between 1999 and 2001, my research revealed something not previously understood about euthanasia (Norwood, 2009). First, my study highlights that euthanasia in practice is predominantly a discussion that only rarely culminates in a euthanasia death. Statistics from 2001 indicated that approximately 34,700 people initiated euthanasia discussions with their physicians in the Netherlands, yet only 1 in 10 who initiated requests died a euthanasia death (Wal et al., 2003: 46). In 2005, 28,600 people initiated euthanasia discussions and less than 1 in 10 who initiated requests died by euthanasia. Of total deaths, only 2.8% died by euthanasia or assisted suicide in 2001 and by 2005 that number had dropped to 1.8% (Heide et al., 2007; Onwuteaka-Philipsen et al., 2007; Wal et al., 2003). My findings suggest that 'euthanasia talk' – or communications that were initiated among patients, families, and physicians in the wake of a euthanasia request – serves as a kind of Foucauldian discourse grounded in Dutch cultural and historical norms that shape how people think, feel, and act at the end of life. This led to my second major finding, which exposes an interesting irony – that euthanasia talk in many ways serves a palliative function at the end of Dutch life. People use it in part to plan a euthanasia death, but by engaging in these discussions there is also an important by-product to this type of advance planning, which serves to prolong social connections and stave off social death by providing participants with a venue for processing meaning, giving voice to suffering, and reaffirming social bonds and self-identity at the end of Dutch life (Norwood 2009, 2013).

Euthanasia Talk as Palliative Care in the Netherlands

The Netherlands legalized euthanasia and assisted dying by court decision in 1984 and by law in 2002. The Netherlands has the longest standing legal practice of assistance in dying and is typically held as the model for or against euthanasia and assisted dying policies around the world. Between 1999 and 2001, I conducted an ethnographic study of euthanasia and other end-of-life practices in the Netherlands. What I found was not at all what I expected. I found euthanasia to be a practice largely based in talk – a discussion that rarely ends in a euthanasia death. The Dutch home at the end of life is already full with the presence of home care employees and home visits by general practitioners, but once 'euthanasia talk' is invoked, the Dutch public presence in the home increases – with frequent home visits and discussions orchestrated by the general practitioner with patients and their families around a person's request for euthanasia.

Consider the following typical case of euthanasia from the Netherlands. Mrs Veenstra (not her real name), 72 years of age, was an artist, a mother, and a wife when she was diagnosed with inoperable cancer of the lower intestine, 18 years after multiple successful treatments for cancer. This time her cancer had metastasized and she was given approximately 3 months to live. With the support of her husband and adult children, Mrs Veenstra discussed euthanasia with her general practitioner, making both a verbal and written request in the event that her suffering became too great. When I met her she was living on the ground floor of her home and was being taken care of around the clock by her husband who had refused the help of *Thuiszorg*, the home health agency, because he preferred to care of her himself. She had completed her final course of chemotherapy to prolong her life and had chosen to minimize the use of morphine for as long as possible. She told me she wanted to live "as long as I have pleasure." Mrs Veenstra lived 10 months after receiving her terminal prognosis and after initiating her written request for euthanasia with her doctor. She chose euthanasia after multiple conversations with her family and her doctor at the point when she was no longer able to sit up to do her artwork and when she had nearly constant nausea, vomiting, incontinence, and pain.

The consequence of how euthanasia talk has emerged is powerful. In practice, euthanasia talk, even when it does not end in euthanasia death, offers dying persons an alternate route through the end of life. For the dying person, euthanasia talk offers a way to emotionally manage fear, uncertainty, and isolation caused by the often chaotic course of an end-of-life illness. It gives all participants (patients, families, and physicians) an active role at a time when roles are often at best unclear and at worst diminishing. Euthanasia talk offers an ideal image of death that can be used by families to manage the difficult realities of daily decline and loss and to reaffirm family and societal connections. Ultimately, euthanasia talk has emerged as a kind of palliative practice that affirms and maintains social bonds, keeping people connected to Dutch life even as they die at home.

Terminal and Palliative Sedation

Another category of MBPSL includes cases in which death occurs following an increase of medication to alleviate pain symptoms typically accompanied by an explicit request by the patient. This practice is often called terminal or palliative sedation. As a relatively new category of MBPSL, but not necessarily a new practice, this term is defined differently from country to country and researcher to researcher (Maltoni et al., 2012; Morita et al., 2002; Rietjens et al., 2004). It is defined generally as a palliative practice, offering a patient continuous and deep sedation near the end of life and in response to obvious suffering. Griffiths et al. use a more specific definition, defining terminal sedation as "continuous, deep sedation [that] is accompanied by withholding or withdrawing [of] artificial nutrition and hydration for more than two weeks" and palliative sedation as continuous, deep sedation accompanied with or without artificial nutrition and hydration for less than 2 weeks (Griffiths et al., 2008: 76). However it is defined, alleviating pain at the request of patients near the end of life has been occurring in practice for a long time and, like cases of LAWER, these can be viewed as part of the process of good end-of-life care or not depending on the details of each case (Battin, 2008; Gillick, 2004; Tännsjö, 2004).

Life-Terminating Acts without Explicit Request

Of growing concern is a category of MBPSL called LAWER (Jochemsen and Keown, 1999; Pijnenborg and van der Maas, 1993; Rietjens et al., 2007). Legal sociologist, John Griffiths, describes these as cases in which a patient's life is terminated when he or she is close to death, no longer able to communicate, and appearing to be suffering severely (Griffiths et al., 2008: 181). Not every country collects data on this category of MBPSL and not all deaths within this new category are potentially problematic. In the Netherlands, one of the few countries that regularly collect comprehensive statistical data on LAWER cases, they include in this category: deaths of babies under 1 year of age due to withdrawal of treatments, WH/WD cases and cancer cases in which a lethal drug is used to alleviate suffering, and a small number of long-term coma or persistent vegetative state patients. LAWER appear to be a small portion of deaths compared to WH/WD cases (0.4% LAWER vs 16% WH/WD in The Netherlands 2005, for example), but will require on-going scrutiny as nations work out for themselves the boundaries of good care at the end of life (Griffiths et al., 2008: 154, 181).

Arguments around MBPSL

One recurring criticism of the Dutch euthanasia policy and some other MBPSL policies from around the world is the argument popularly known as the 'slippery slope' argument that claims that allowing physicians to conduct euthanasia or assisted dying may eventually lead to patients being killed against their will (Foley and Hendin, 2002; Gillick, 2004; Hendin, 1997; Keown, 2002). Arguments suggesting the presence of a slippery slope in the Netherlands contend that cases of LAWER and terminal sedation where there is an intention by the physician to hasten death are examples of a slippery slope in effect (Hendin, 2002: 97–106). Others suggest that these practices are similar to rates found elsewhere in Europe, that not all cases of LAWER and MBPSL are the same, and that many of these life-terminating behaviors constitute long-standing 'normal medical practice' in the Netherlands and elsewhere (Griffiths et al., 2008: 180–181).

The problem with many of these arguments for and against MBPSL is that they tend to cite data that originate largely from retrospective quantitative surveys and interview-based studies that do not allow researchers an understanding of these behaviors in day-to-day practice. If you look more closely at the types of choices that people are making at the end of a medicalized life, you see that end-of-life discourses exist in many cultures in many places, shaping how people participate in the end of life. Euthanasia talk is just one Dutch discourse at the end of life. End-of-life talk takes many forms in many places and these discourses can be powerful in shaping choice.

Looking at what the Dutch do at the end of life demonstrates one cultural response to restore a 'natural' ideal at the end of life, and a trend that is beginning to gain momentum around the Western industrialized world. Euthanasia policy and euthanasia talk in the Netherlands have allowed Dutch people to replace the image of an isolating, highly medicalized trajectory with an ideal image where family members are assembled bedside in the home and the loved one slips painlessly into death with the help of a trusted physician. The fact that euthanasia deaths rarely occur in reality does not seem to matter. But while this image may be based on a 'natural' ideal where machines and interventions do not dominate the end of life, the act of euthanasia clearly is not natural. It is more than simply unplugging machines and withdrawing interventions; it is replacing one cultural intervention with another (Norwood, 2013).

Future Directions and Alternative Choices at the End of Life

While medicalization of the end of life may dominate, there are other alternative choices that are working to transform how people around the world experience the end of life. Some would argue that less medical attention and more caring for the social person is what is called for at the end of life and there are

a number of nonmedical approaches to dying that are gaining momentum. Palliative care and hospice are on the rise in the US, Europe, and in other places around the world and are beginning to offer a real alternative to medicalized ways of dying. Palliative care, also called comfort care, varies extensively from place to place (Broom et al., 2012; Bruera et al., 2000; Hendry et al., 2013; Higginson et al., 2003; Kellehear, 2000; Lawton, 2000). In some places, palliative care may simply be a retooling of medical care to focus on relieving symptoms and pain management just in the final hours and days of life once all curative measures have ceased; in other places, however, it encompasses something broader – prolonged practices that strive to address the needs of the whole person, including spiritual, existential, emotional, as well as physical needs at and near the end of life. Palliative care is limited, however, in places like the US where it is largely a retooling of medical care, and hospice is equated with the final hours and days of dying. When this occurs, palliative care and hospice are accessed too late in the life course to offer a real alternative to medicalized dying. In places like the Netherlands, however, where whole-patient tenets of palliative care were never extricated from what primary care physicians do, broader forms of caring within the medical establishment exist, offering Dutch people of all ages access to more holistic care throughout the life course (Norwood, 2009: 93–94).

A resurgence of hospital chaplains and spirituality in health care in recent times offers another alternative to the medical pathway at the end of life (Aldridge, 2000; Cadge, 2013; Kellehear, 2000; Puchalski, 2006; Young and Koopsen, 2010). The modern-day chaplains are immersed in a world of hospital medicine, but at the margins they have been able to reestablish a place at the bedside of the sick and dying. In an ethnographic study of hospital chaplaincy in 1997, I found chaplains who were able to forge a strategic, if ambivalent, existence within hospital medicine by alternately embracing and distancing themselves from competing discourses of religion and medicine in order to offer patients what medicine cannot. They bear witness; they bring skin-to-skin touch and comfort through religious ritual at a time when medical treatments are no longer viable. Processing what it means to die, once largely the domain of priests, chaplains, and religion, now rests in many hospitals in the hands of all-faith chaplains who (when skilled) listen without proselytizing and witness without imposing their own agenda (Norwood, 2006a).

Finally, home- and community-based supports for persons who are aging and living with chronic illness and decline are on the rise in Europe and in the US. In the United States, for example, new supports are emerging boosted in part by the passage of the Patient Protection and Affordable Care Act of 2010. These supports are designed to keep more people at home or in community-based settings and are designed increasingly around holistic, person-directed models of long-term care (Gleckman, 2009; SAL, 2001; Thomas, 1996). In places around the US, for instance, there are a number of grassroots organizations designed to help keep people as they age in their own home or community. The Village movement is a community-driven initiative where neighborhoods of persons who are aging band together, paying annual membership fees to support an executive director and office space. Members then have only to request assistance – a ride to the grocery store, assistance picking up prescriptions, or help accessing home health services or supports – and organized volunteers from the community provide these services (Gleckman, 2009: 122–124). When persons can no longer live at home on their own, assisted living has emerged in places around Europe and the US to offer a very different model of residential care compared to the more traditional medical model nursing home. Pioneered in the US by Paul and Terry Klaassen, founders of *Sunrise Senior Living* and expanded by Bill Thomas through the *Eden Alternative* and the *Green House Project*, not all assisted living are created alike. Assisted living can vary from small, eight-person group homes to large facilities, but most are predicated on a founding philosophy exemplified by the Eden Alternative that emphasizes 'person-centered' care, choice, companionship, and dignity over the more traditional medical-model of long-term care (Thomas, 1996: 9). Unfortunately in the US, not everyone has equal access to these home- and community-based alternatives. Home health services are not utilized enough and government-subsidized long-term care for the indigent, Medicaid, cannot currently be used to pay for most assisted living so it remains for the time being for those who can afford to pay.

As people age, they need supports that will help them maintain not only their physical body, but their social being. In a recent study of innovations in long-term care, I found that the ability of persons to participate in reciprocating relationships through the exchange of 'gifts' is a critical part of maintaining social bonds and social life in long-term care. Using anthropologist Marcel Mauss' concept of gift exchange (1967), I found that long-term care environments that foster self-determination, social connection, and reciprocity in relationships help residents maintain a good quality of social life and alternately prevent premature social death – or death of the social being. Even giving the simplest of gifts can foster social connection – from participating in cutting vegetables for dinner, to helping a fellow resident cross a room, to listening to someone tell a story of their life. It is these types of 'gifts' that help people maintain social life and make long-term care settings more like home, particularly near the end of life (Norwood, forthcoming).

For those who cannot (or do not wish to) avoid medicalized ways of dying, choices are also being transformed within medicine. Around the world, health systems are feeling the pressure as more baby boomers age and live longer with chronic conditions. With the increasing cost of end-of-life care – some of the costliest care persons receive (Lynn, 2004: 1–10) – policy makers and other key stakeholders are being forced to make difficult choices in the provision of health and long-term care. In the US, for example, the Patient Protection and Affordable Care Act, or Obamacare as it is popularly named, brings with it a culture of medical change as insurers, hospitals, clinics, and providers around the country are called on under a number of initiatives to improve health care – improving access to health care, improving health outcomes, improving quality of care, while reducing overlap and overall cost of care. While the full impact of this legislation is not

clear, what is clear is that medical practices in the US are changing as a result. At the end of life, this is likely to mean shifts toward home- and community-based solutions and a growing shift away from institutionalized care, such as the traditional nursing home model.

Natural process and cultural intervention pervade end-of-life choices and nature and culture really cannot exist without the other. End-of-life choices around the world exist, but largely exist among a culturally restricted set of options. This is what causes people like Mr Carter and the many others like him to die deaths that are not what they or their family envisioned and worse – hooked up to machines, dying in hospitals, experiencing CPR, and other aggressive forms of intervention in the final days of what they had hoped might be a more peaceful passing. That death – or at least ordinary, everyday dying – is denied to some extent in many places in the modern world is probably true. It is what leaves people like Mr Carter without a medically or culturally supported place to contemplate how he ideally wanted to live prior to his death. It left him with few people to talk to, with little time to process, and without a clear understanding of his medically constructed options. The result for many who die similar deaths around the world is a death without real choices.

Sociologist William Bogard may be right – that choice at the end of life is in part an illusion, and instead how many people in highly industrialized societies die is largely a factor of medical discourses exerting social control to modulate the course of modern life (Bogard, 2008). We die these highly medicalized deaths because that is the current dominant discourse on dying. In many Western industrialized nations our choices are medically mediated choices, offering dying persons and their families mostly institutionalized, aggressive, futile, and painful options for sustaining dying bodies often without regard to the physical, emotional, spiritual, and social suffering that is caused. Death may be a natural event, however treatment of death and dying and the choices that flow from that are largely cultural. Still, at the borders of dominant discourses, human agency and competing discourses are forging alternative pathways. While choice may always be somewhat restricted by cultural mediation, new choices are emerging and competing with dominant discourses to alter and change the practices and meanings of how people around the world die.

Abstract

The nervous and endocrine systems are involved in a large degree of cross-talk, and are intricately linked in both structure and function. The brain regulates the secretion of endocrine hormones, which in turn have profound effects on brain and behavior through the abundant hormone receptors in the central nervous system. Therefore, it is not surprising that steroid hormones are implicated in the etiology, manifestation, and treatment of psychiatric illness. Here, we focus on stress and gonadal hormones and their roles in depression, bipolar disorder, and schizophrenia.

Despite decades of research, our knowledge around the etiology and pathophysiology of psychiatric disorders is incomplete. More importantly, available pharmacotherapies are effective in only a subpopulation of patients, and therefore efforts to discover new and improved drug targets are ongoing. However, considerable evidence has emerged in support of the involvement of the neuroendocrine system in various psychiatric disorders. In particular, there is a growing recognition of the sex differences in incidence, symptoms, and efficacy of treatment, which have been largely ignored in the literature thus far. Given these sex differences, it is perhaps not surprising that gonadal hormones are implicated in many neuropsychiatric disorders. Here, we focus our discussion on two major neuroendocrine systems: the hypothalamic–pituitary–adrenal (HPA) axis, and the hypothalamic–pituitary–gonadal (HPG) axis, both of which are implicated in the etiology, manifestation, and treatment of several psychiatric disorders, including depression, bipolar disorder, and schizophrenia.

Cross-Talk between the Nervous and Endocrine Systems

Both structurally and functionally, the nervous and endocrine systems are intimately connected. Largely through the hypothalamus, the central nervous system (CNS) regulates the release of hormones from the pituitary gland at the base of the brain. In turn, pituitary hormones regulate a variety of physiological processes directly by acting on target tissue, or indirectly by inducing the secretion of hormones from other endocrine glands. Besides acting on target tissue, hormones can bind to receptors at various levels of the neuroendocrine system, allowing for the recognition and regulation of circulating hormone levels, as further described below in the case of the HPA axis. As a result of this relationship between the nervous and endocrine systems, we are able to gain unique insights into the functioning of the relatively inaccessible CNS through circulating levels of hormones.

The HPA Axis and Negative-Feedback Regulation

In response to a real or perceived stressful event, the HPA axis is activated, and as a result, there is an increased release of glucocorticoids from the adrenal glands into the bloodstream. Cortisol and corticosterone, in humans and rodents, respectively, are main glucocorticoid hormones involved in the biological stress response. In the face of threat, activation of the HPA axis is essential, as glucocorticoids mobilize energy stores to prepare to deal with the stressors such as escaping from danger. The stress-induced HPA activation is a multistep hormonal process, initiated at the activation of neurons in the paraventricular nucleus (PVN) of the hypothalamus. When activated, the PVN secretes corticotropin-releasing hormone (CRH), which in turn acts on the anterior pituitary gland, inducing the release of adrenocorticotropic releasing hormone (ACTH) into the bloodstream. Finally, ACTH acts on the medulla (the inner portion) of adrenal glands, stimulating the release of glucocorticoids. The action of glucocorticoids is not limited to the activation of the stress response; they also play a critical role in the termination of that same response. In a negative-feedback loop, elevations in glucocorticoid levels are detected, in large by the hippocampus, which in turn signals the hypothalamus to suppress further release of CRH. This negative-feedback inhibition is essential as it prevents prolonged exposure of tissue to high levels of glucocorticoids. Prolonged exposure to high levels of glucocorticoids is grossly detrimental to health.

The HPG Axis

In a multistep hormonal cascade similar to that described for the HPA axis, the HPG axis is a neuroendocrine system that regulates the release of gonadal hormones from the gonads (ovaries or testes). The functions of gonadal hormones extend well beyond regulating sexual and reproductive functions, to include effects on mood and cognition among other CNS processes. These effects are primarily mediated through gonadal hormone receptors that are found in abundance throughout the brain, and in the limbic system in particular, including the hippocampus. It is important to note here that sex differences in disease prevalence, symptomology, or treatment can point to an involvement of gonadal hormones in the disease process. Implications of gonadal hormones in neuropsychiatric disorders may be due to their involvement in the pathophysiology at early stages (during development), later in life (during adolescence or adulthood), or both.

Neuroendocrine Involvement in Mood Disorders

In the following section, we discuss the significant neuroendocrine changes that are associated with depression and bipolar disorder, two of the most prevalent and serious psychiatric mood disorders. We summarize findings from the literature suggesting that HPA and/or HPG changes may be linked to the risk for, symptom profile, and treatment of these disorders.

Stress, HPA Function, and Depression

While the etiology of depression is not fully understood, mounting evidence suggests that chronic stress exposure is intimately linked to the development of the disorder (reviewed in Tennant, 2002). The HPA axis plays a key role in regulating the biological response to stress, and as such, it is not surprising that HPA axis dysfunction is a biomarker of depression (reviewed in Stetler and Miller, 2011). There are major differences in HPA function between depressed and nondepressed individuals, the first of which is elevated circulating cortisol levels in depression. Additionally, the characteristic diurnal rhythm of cortisol secretion, which features distinct cortisol peaks in the morning and evening, is dampened in depressed individuals. Importantly, the ability of the HPA axis to self-regulate, that is, to recover after a stress response via the negative-feedback system, is also compromised in depression. The integrity of the HPA negative-feedback system can be evaluated using the dexamethasone (DEX) suppression test. This medical test utilizes DEX, a synthetic glucocorticoid, which essentially mimics the endogenous cortisol in the negative-feedback system of the HPA axis. Therefore, when administered to healthy individuals, DEX reduces HPA activity and suppresses the release of cortisol. In many depressed individuals, however, DEX fails to suppress cortisol release, indicating a faulty negative-feedback system (Ising et al., 2007).

Because HPA dysfunction is the best described biological endophenotype associated with depression, restoration of its function could be a central drug target. In fact, commonly prescribed antidepressant medications are effective in restoring HPA disruption only in patients who respond favorably to treatment. In other words, antidepressant alleviation of depressive symptoms seems to be linked to a restoration of HPA dysfunction. Temporally, this restoration coincides with, or just precedes, the relief from depressive symptoms (Ising et al., 2007). This indicates that in treatment responsive patients, HPA dysfunction may be central to the pathophysiology of the disorder. In order to gain a better understanding of the relationship between stress, depression, and HPA dysfunction, researchers use animal models of depression to assess relevant brain, behavioral, or neuroendocrine phenotypes (reviewed in Yan et al., 2010). Two well-established animal models that show considerable validity and reliability are the chronic variable stress model and the chronic corticosterone administration model. Interestingly, the neuroendocrine changes demonstrated in these models are similar to those observed in depression patients. Such experimental models are fundamental in understanding the etiology of the disorder, the mechanisms of antidepressant action, and in the development of novel treatments.

Sex Differences in Depression

Of the most robust epidemiological findings in depression is the higher prevalence of the disorder in women, consistent across cultures studied, typically here is a prevalence ratio of at least 2:1 for women to men for major depressive disorder (Gutierrez-Lobos et al., 2002). This sex difference in prevalence arises at puberty, declining after the age of 50, and is most striking during women's reproductive years. Specifically, the postpartum and perimenopause are two periods in a women's life wherein the risk of depression is largely increased (Cohen et al., 2006; Hendrick et al., 1998). Interestingly, these two periods are associated with dramatic fluctuations in gonadal and/or stress hormones. While many hypotheses, both biological and psychosocial, have attempted to explain the sex differences in depression, the best supported are neuroendocrine theories highlighting the role of gonadal hormones (Hammarstrom et al., 2009). In addition to the higher prevalence of depression in women, there are differences in the presenting symptomology between men and women. For example, women are more likely to develop atypical depression, which is characterized by excessive fatigue, hypersomnia, and/or hyperphagia (Young et al., 1990; Silverstein, 2002), and are more likely to have comorbid anxiety (Sloan and Kornstein, 2003; Keers and Aitchison, 2010).

Gonadal Hormone Levels Are Associated with Depression and Its Treatment

Perimenopause is a 10-year period of transition into menopause, involving dramatic hormonal changes leading to a permanent state of hypogonadism, that is, diminished levels of gonadal hormones. Women with or without a previous history of depression are at an increased risk of developing the disorder in this period (Freeman et al., 2006), suggesting that the associated hormonal changes are involved in the disease. However, it should be noted that there is rarely a direct association between serum levels of ovarian hormones and depression ratings. In men, levels of gonadal hormones are also associated with depression. This is evident from correlational studies showing that both younger and older depressed men have lower levels of testosterone, the main testicular hormone in men (McIntyre et al., 2006). Furthermore, the prevalence of depression is greater among hypogonadal men. Additionally, in both men and women, gonadal hormone levels are linked to antidepressant efficacy. For example, in postmenopausal women diagnosed with depression, selective serotonin reuptake inhibitors (SSRIs) are more effective in relieving depression symptoms when prescribed alongside hormone therapy (HT) (Thase et al., 2005). Similarly, testosterone as an adjunct therapy in depressed hypogonadal men is effective in boosting the efficacy of antidepressants, as shown by a meta-analysis (Zarrouf et al., 2009). Taken together, it is clear that low levels of gonadal hormones in both men and women are associated with depression, and possibly resistance to antidepressant treatment. Moreover, in depressed hypogonadal men or women, HT may be an effective adjunct therapy.

Interestingly, the ability of antidepressants to ameliorate depression symptoms is dependent on sex, where SSRIs are more effective in women, and tricyclic antidepressants (TCAs) are more effective in men (Keers and Aitchison, 2010). This

implies that gonadal hormones, and/or chromosomal differences, may be important for antidepressant efficacy beyond the context of hypogonadism. Moreover, the capability of antidepressants to restore HPA axis function shows a disparity by sex, in which the ability to normalize HPA negative-feedback dysregulation is better associated with remission in women as compared to men (Binder et al., 2009). Although beyond the scope of this article, this difference may be in part modulated by the well-established interactions between the HPA and HPG axes.

Gonadal and Stress Hormones in Postpartum Depression

The postpartum period marks the time of greatest risk for developing depression in women. In fact, postpartum depression (PPD) affects a striking estimate of 15% of women (Wisner et al., 2013). Apart from the delirious effects on the well-being of mothers, PPD is associated with poorer cognitive, social, and emotional outcomes for children of affected mothers. Importantly, pregnancy and postpartum are coupled with dramatic neuroendocrine changes, mainly in HPG and HPA hormones, and some of which are amplified by the placenta. In terms of HPA function, pregnancy and postpartum are associated with elevated cortisol levels, and blunted diurnal patterns of peak cortisol release. Intriguingly, this hormonal profile is similar to that commonly observed in depressed patients, as we discussed previously. This suggests that pregnancy-related changes in HPA function may contribute to the increased risk of depression for women in this period. On the other hand, changes in ovarian hormones include dramatic increases of estrogens (notably estradiol and estriol) throughout gestation, with estradiol reaching levels 200 times normal level at week 20 of gestation, and a sudden prolonged drop in estrogens after delivery of the placenta (itself an endocrine gland). Indeed, postpartum women are considered hypogonadal for up to 180 days after parturition. These dramatic fluctuations in hormones led to the development of the 'ovarian hormone-withdrawal' hypothesis of PPD. This hypothesis proposes that the elevated levels of estrogens during pregnancy, followed by the sudden hypogonadal state post-delivery may play a role in the etiology of PPD. In support of this hypothesis, studies have shown that hormone-stimulated estradiol withdrawal led to a significant increase in depressive symptomology and enhanced cortisol release in nondepressed women with a history of PPD when compared to nondepressed women without a history of PPD (Bloch et al., 2000, 2005). This illustrates that women who develop PPD may be more vulnerable to the effects of pregnancy-related changes in HPG hormones, although what underlies this vulnerability remains unclear. Animal models of PPD are important for enhancing our understanding of the unique female physiology related to pregnancy and postpartum, and how it relates to the increased risk for depression. In an attempt to mimic the human condition, such models emphasize the role of stress and sex hormones. For example, the chronic administration of corticosterone to rats in the postpartum period increases depressive-like behavior in the mothers, and decreases maternal behavior toward her pups, while withdrawal from a hormone-simulated pregnancy increases depressive-like behavior and decreases hippocampal plasticity (reviewed in Brummelte and Galea, 2010).

HPA and HPG Involvement in Bipolar Disorder

Bipolar disorder has a lifetime prevalence of approximately 4%, and is characterized by episodes of mania or hypomania, alternating with periods of depression. In a similar, but more exaggerated pattern to that seen depression, individuals with bipolar disorder present with indicators of HPA dysfunction (reviewed in Daban et al., 2005). This includes elevated basal cortisol and negative-feedback dysregulation as measured by the failure of DEX to suppress cortisol. However, while treatment-associated alleviation of symptoms is linked to the restoration of HPA function in depression, the same relationship is not apparent in bipolar disorder. Lithium-treated bipolar patients in remission still exhibit elevated levels of cortisol and negative-feedback dysregulation, suggesting that HPA dysregulation may be at the core of the disorder, or alternatively that lithium treatment acts on a different disease-associated system. Interestingly, the pattern of HPA dysfunction may be predictive of future manic/hypomanic relapse in patients with bipolar disorder. This has been shown in a CRH stimulation study carried out in stable medicated bipolar patients, where exogenous CRH resulted in higher ACTH levels in patients that relapsed 6–12 months following the test (Vieta et al., 1999), indicating a higher sensitivity of the pituitary to CRH prior to relapse.

Unlike depression, which is a unipolar mood disorder, there does not seem to be a clear sex disparity in the lifetime prevalence rates of bipolar disorder. However, there are differences in the manifestation of the disorder between men and women, and in periods of vulnerability, suggesting that gonadal hormones are still important to consider for a holistic understanding of the disease underpinnings. As reviewed by Diflorio and Jones (2010), sex difference in bipolar disorder are apparent in the subtypes and clinical presentation, including a higher prevalence of type II diagnosis (hypomania predominant), and a higher likelihood of mixed and rapid cycling episodes in women. Interestingly, in women with bipolar disorder, gonadal hormone levels may be linked to the severity of symptoms or the recurrence of bipolar episodes. Suggestive of this are findings showing a significant number of women with bipolar disorder having increased symptoms in the perimenopausal period (Marsh et al., 2009), when ovarian hormones begin to decline prior to the onset of menopause. Additionally, postmenopausal women with bipolar disorder who are not taking HT are more likely to experience a worsening of symptoms after menopause in comparison to women taking HT (Freeman et al., 2002). More evidence linking levels of female gonadal hormones to the disease manifestation comes from the literature studying bipolar women during postpartum, which is a period associated with an especially high risk of severe episode recurrence (Jones and Craddock, 2001).

Neuroendocrine Involvement in Schizophrenia

Schizophrenia is a serious psychiatric disorder that affects approximately 1% of the population. It is characterized by positive symptoms (including hallucinations and delusions), negative symptoms (such as social withdrawal, flat affect, and poverty of speech), and cognitive impairments (such as

memory, executive function, and attention deficits). The etiology of schizophrenia is complex and heterogeneous; however, amassing evidence suggests an interaction of genetic vulnerabilities and environmental factors in the pathogenesis of the disorder. In the following section we present evidence of significant HPA and HPG involvement in schizophrenia.

Stress, HPA Function, and Schizophrenia

Unlike in depression, large population studies do not show a clear relationship between exposure to stress and risk for developing schizophrenia. That is, on average, individuals with a diagnosis of schizophrenia do not have a history of more severe or frequent stress exposure than the healthy population. However, as reviewed in Walker et al. (2008), there is strong evidence illustrating that stressful life events often precede relapse of psychotic episodes and exacerbate symptoms in schizophrenia patients. Moreover, in individuals with a high genetic risk of developing schizophrenia, that is, those with a family history of the disorder, exposure to stressful life events is linked to a higher likelihood for a future diagnosis of schizophrenia. Taken together, this suggests that in individuals predisposed to the disorder, stress-induced activation of the HPA axis may trigger vulnerable neural substrates related to schizophrenia.

A body of literature shows signs of HPA dysfunction in schizophrenia patients (reviewed in Walker and Diforio, 1997), the first being elevated baseline levels of cortisol and ACTH. This effect is seen in first-episode and chronic patients, and is especially evident in nonmedicated patients. Moreover, elevations in cortisol are correlated with an exacerbation of negative symptoms. Both typical and atypical antipsychotics have a restorative effect of HPA function, whereby they have been shown to reduce elevations in cortisol and ACTH. Interestingly, antipsychotic drugs are more effective in alleviating symptoms in patients presenting with more profound cortisol elevations prior to the initiation of treatment (Ritsner et al., 2005). This indicates that antipsychotic drugs may target HPA dysfunction through the suppression of the HPA axis. In addition, HPA dysfunction may be at the root of the disorder in a subpopulation of patients, further emphasizing that schizophrenia is a largely heterogeneous disease.

Sex Differences in Schizophrenia and the Role of Gonadal Hormones

While the onset of schizophrenia is typically in late adolescence/early adulthood, individuals who go on to develop the disorder often present with a period of social, behavioral, and cognitive decline during early adolescence, suggesting that the manifestation of the disorder coincides with a time of considerable changes for HPG function and maturation of HPA axis. Interestingly, there are clear sex differences in the lifetime prevalence rates of schizophrenia, in which men are approximately 40% more likely to develop the disorder than women (McGrath et al., 2004). Additionally, the course of illness shows distinct differences between men and women. Although the onset of schizophrenia is typically late in adolescence/early adulthood for both sexes, the average age of onset in men is 3–4 year prior to that in women (Munk-Jorgensen, 1987). In other words, the peak onset is earlier and steeper in men than in women. Intriguingly, women also have a second peak in incidence rate during late perimenopause, or the mid-late 40s, which is not seen in men around the same age. This pattern of incidence rates across the lifespan leads to hypotheses suggesting that estrogens, such as estradiol, which are more abundant in women, may play a protective role against the development of schizophrenia. There is also evidence that in schizophrenia patients, temporal lobe volume is decreased in men but not in women (Bryant et al., 1999), which may be a neural correlate of the fact that men with schizophrenia are more likely to present with more severe cognitive disturbances than women with schizophrenia.

Providing support for the hypothesis that estrogens play a protective role in the disease is a plethora of data linking levels of ovarian hormones to the onset and severity of symptoms. For example, in patients diagnosed with schizophrenia, an earlier onset of puberty is linked to a delayed onset of the disorder in women only (Cohen et al., 1999). Interestingly, pregnancy is associated with a reduction of symptoms, and this effect may be attributed to the dramatic increase of estrogens throughout gestation. Furthermore, the psychotic symptom severity in women diagnosed with schizophrenia varies alongside the menstrual cycle (Bergemann et al., 2007). That is, psychotic symptoms are exacerbated around menstruation, which is the period during a women's menstrual cycle with the lowest circulating levels of estradiol. Additionally, levels of ovarian hormones may have important implications in the treatment of the disorder. In fact, there is evidence suggesting an interaction between gonadal hormone levels and antipsychotic efficacy in women. For example, in antipsychotic-treated postmenopausal women with schizophrenia, HT was associated with a lower prescribed dose of antipsychotic treatment, and independent of antipsychotic dose, HT was also associated with less severe negative symptoms (Lindamer et al., 2001). Hence, as an adjunct therapy, HT may improve prognosis for postmenopausal women with schizophrenia. Altogether, these data suggest that there is an inverse relationship between levels of female gonadal hormones and severity of schizophrenia symptoms, with higher levels of gonadal hormones correlating with less severe symptom presentation.

If ovarian hormones in women reduce the vulnerability threshold for developing schizophrenia, then it would be reasonable to expect that women with schizophrenia will have lower mean levels of gonadal hormones when compared to women without the disorder. In fact, this has been supported by studies in which circulating estradiol levels were measured across several menstrual cycles in schizophrenia patients, and were found to be lower than the control population across all phases of the menstrual cycle (Riecher-Rossler et al., 1994). From these data, however, it is not possible to interpret the directionality of this relationship. That is to say, it is not clear whether lower levels of estradiol precede the illness and constitute a risk factor, or represent a consequence of the disorder. Building on this evidence of hypogonadism in premenopausal women with schizophrenia, several placebo-controlled clinical trials tested the efficacy of estradiol as an adjunct therapy in the alleviation of symptoms. These studies showed that estradiol paired with antipsychotic treatment resulted in a more rapid and more effective alleviation of

symptoms in comparison with antipsychotic treatment alone (Kulkarni et al., 1996; Akhondzadeh et al., 2003). Therefore, this indicates that HT may be an effective adjunct therapy in both pre- and post-menopausal women with schizophrenia.

From the statistics showing a higher prevalence of schizophrenia in men, it can be speculated that, rather than estrogens being protective in women, the more abundant testosterone in men may contribute to their vulnerability. For this speculation to hold merit, we should expect to see elevated levels of testosterone in men with schizophrenia; however, the evidence suggests otherwise. In fact, men with schizophrenia are reported to have lower or equal mean testosterone levels in comparison to men without the disorder. Moreover, in men with schizophrenia, there is a correlation between the severity of negative symptoms and circulating testosterone levels, where lower testosterone levels are found in patients presenting with more severe negative symptoms (Shirayama et al., 2002). Therefore, similar to the data in women, hypogonadism seems to be associated with schizophrenia in men, and the question of whether this effect precedes or result from the disorder is similarly unclear. Moreover, there is evidence suggesting that testosterone is effective as an adjunct therapy as it boosts the effects of antipsychotic medication to alleviate negative symptoms of schizophrenia in men (Ko et al., 2008).

Endocrine Disorders and the Risk for Psychiatric Illness

So far in our discussion, we provide examples of endocrine dysfunction associated with a primary diagnosis of psychiatric illness. However, the inverse relationship also exists, where a primary diagnosis of endocrine illness can be associated with an increased risk of developing psychiatric disorders. A prime example of this relationship comes from Cushing's syndrome, which regardless of etiology is characterized by chronically elevated levels of glucocorticoids. The most common cause of Cushing's syndrome is pituitary tumor (adenoma), resulting in an excess secretion of CRH. As reviewed in Sonino and Fava (2001), Cushing's syndrome is associated with a high prevalence rate of depression, episodes of mania or hypomania, and anxiety disorders. Interestingly, a restoration of HPA function, for example through surgery in the case of pituitary adenoma, is effective in the alleviation of psychiatric symptoms. Thus, findings from the psychiatric comorbidities in Cushing's syndrome provide important support for the strong relationship between endocrinology and psychiatry.

Conclusions

The literature we overview here, with a focus on depression, bipolar disorder, and schizophrenia, suggests that significant neuroendocrine changes are associated with psychiatric disorders, and that neuroendocrine dysfunction may lie at the core of the etiology and pathophysiology of these disorders, in at least a subpopulation patients. The functional interaction between the nervous and endocrine systems provides a unique window into the CNS, and allows for endocrine hormones to be useful as biological markers for psychiatric disorders, ultimately aiding our understanding of disease underpinnings and enhancing treatment prospects.

We summarize our discussion in three major themes:

- Stress is a risk factor for the development of psychiatric disorders in vulnerable individuals, and is associated with relapse and exacerbation of symptoms. Additionally, a hyperactive HPA axis and HPA negative-feedback dysregulation are well-documented neuroendocrine changes associated with all psychiatric disorders discussed here. Therefore, HPA dysfunction is an important target for the development of novel pharmacotherapies.
- There are many sex differences in the prevalence rates, clinical presentation, and treatment outcomes of psychiatric disorders, and the unique physiology of women is important to consider in this context. As such, understanding the role of gonadal hormones in various aspects of the disease mechanism is essential to the development of individualized, effective, and safe pharmacotherapies for both men and women.
- Gonadal hormones have protective effects on mental health in both men and women, and are implicated in the treatment of psychiatric illness. This was demonstrated in the discussion of periods where low levels gonadal hormones in women are associated with an increased risk for, or exacerbated symptoms of psychiatric disorders (i.e., perimenstruation, postpartum, and post-menopause). Similarly, hypogonadism is associated with psychiatric disorders in men, and may be associated with more severe symptoms. Finally, in hypogonadal men and women, there is evidence that HT is an effective adjunct therapy alongside traditional treatment for psychiatric disorders.

Abstract

Explanation and examples are given of the distinction between endogenous and exogenous variables. The concept of endogeneity arises when a distinction is made between a dependent variable, to be explained, and independent variables, used as explanatory factors or inputs. A variable is often labeled exogenous or independent if it is used to explain variations in the endogenous or dependent variable. There are various forms of endogeneity, such as in recursive versus interdependent systems. The role of endogeneity in social science empirical research is discussed. Examples of recursive and interdependent systems are given.

Endogenous versus Exogenous Variables

In several fields in the social sciences a distinction is made between endogenous and exogenous variables. A simple example may clarify. In studies of social inequality researchers try to explain differences in the level of education that people achieve. Education can be measured, for example, as years of schooling or as less than high school, a high school degree, and so forth. The goal of social science analysis will then be to figure out how the level of education achieved varies with other characteristics, such as a person's social background, sex, race, and more. Social background can be measured in terms of parents' socioeconomic status or income. An early example of this kind of analysis in sociology is Blau and Duncan (1967).

In this example, level of education is the endogenous variable. The variables used to explain variations in the level of education are called exogenous. More generally, the variables that show differences we wish to explain are called endogenous, while the variables used to explain the differences are called exogenous. Often this goes along with a causal imagery. Exogenous variables are thought of as causes, endogenous as their effects. But there is no necessary connection; one may use the terms without implying causality (Sobel, 1995). A simpler terminology for exogenous and endogenous is independent and dependent variables.

This distinction between exogenous and endogenous variables is used almost universally in quantitative social science. It arises in statistical data analysis, as in large parts of sociology, political science, and psychology. It arises also in mathematical analysis of theoretical ideas, as in large parts of economics and some parts of political science. But the distinction clearly is of relevance also in more qualitative research, such as in fieldwork and historical research, though less often used explicitly in those contexts. The distinction is simply relevant whenever there is some phenomenon that the researcher is trying to explain, which then is the endogenous variable, and there are some explanatory factors that are used to explain the phenomenon, which then are the exogenous variables. For example, in Skocpol's (1979) study of social revolutions, two exogenous variables are the state and agrarian structures in a society, while the endogenous is whether a revolution occurs or not.

Recursive Systems: Causal Chains

The example above can be elaborated. Consider what happens once people have achieved a particular level or type of education. They then often enter the labor market hoping to find a job. But the kinds of jobs people can expect to get depend strongly on their education. Psychologists are not hired to build bridges and engineers are rarely employed to provide mental-health services to children in despair. So in a next step, in explaining the kinds of jobs people find, education becomes an important independent or exogenous variable. It was endogenous, but is now an exogenous variable for explaining the type of job, which then is the endogenous variable. But the job may in turn become an important factor, thus exogenous, in explaining the salary received, which then is the endogenous variable.

And so it may continue. A variable, which once was endogenous, may be exogenous in another setting. There is a technical term for such reasoning, not important in itself, but sometimes encountered (from Bentzel and Wold, 1946; see Hausman, 1998). The variables entering into the reasoning are said to constitute a 'recursive system': parents' socioeconomic status influences education, education influences the type of job, the type of job influences earnings and career opportunities, and so forth. In causal imagery, they make up a causal chain. And it may also be that parents' socioeconomic status not only influences education, but also the job their offspring gets, for example through the network ties parents may have to employers or others who make hiring decisions. So an exogenous variable may be exogenous not only to one of the endogenous variables but to several of them.

For a set of variables to constitute a recursive system, there can be no feedback effects between them. Education may influence the type of job. But the type of job can have no influence on education itself. That such is the case is almost always tautologically true, provided the problem is carefully framed. The level of education is determined chronologically prior to the type of job, so there can be no feedback effect. This does not rule out that expectations and desires about future jobs will influence the education sought. But expectations about the future are not the same as the future. Enough of us have desired to be glamorous rock stars, outstanding violinists,

famous war generals, or influential academics. Some may even have sought educational tracks correspondingly. A few succeed, most end up other places than aimed for. But whatever education and training we acquire, it usually has some impact on where we end up, though not always enabling us to get where we aspired to.

Statistical versus Mathematical Analysis

Often the analysis of the relationships between variables is statistical. Researchers then typically use multivariate statistical methods. One tries to assess the joint influence of, say, sex and race on earnings. The goal is to see how the average level of earnings varies with sex, race, and so forth, not to explain the outcome for each individual. Similarly, if the endogenous variable is the type of job, say blue-collar, white-collar, professional, etc., then the goal of the analysis is to figure out how the percentages falling into each of these groups vary with education, sex, race, etc. Statistical social science analysis is eminently Holmesian, taking its cue from Sherlock Holmes. He argued that "while the individual man is an insoluble puzzle, in the aggregate he becomes a mathematical certainty. You can, for example, never foretell what any one man will do, but you can say with precision what an average number will be up to. Individuals vary, but percentages remain constant. So says the statistician" (Doyle, 1986: 175). And though few quantitative social scientists would accept the statement that aggregate relationships are a mathematical certainty or that we can successfully predict aggregate behaviors, the gist of Holmes' comment is correct and agreed upon: We investigate what on average goes on.

If the analysis is purely mathematical, where one tries to explore theoretical ideas by means of mathematical tools, then the writer traces out the logical implications of the relationships between the variables. For instance, from the knowledge of how producers and consumers act and interact in modern economies, economists will specify several mathematical equations that try to capture elements of these actions and interactions. A goal can be to investigate, using the mathematical equations as an aid for reasoning, what the impact of an increase in the interest rate will be for consumption, production, and finally the national product. For example, increasing the interest rate may lead to a decline in home sales, leading to a decline in building of new homes, with correspondingly increased unemployment in the home construction sector, and so forth.

Interdependent Systems: Mutual Dependencies

In some settings two or more variables may mutually influence each other, sometimes referred to as being interdependently related, constituting an interdependent system. For example, the amount of schooling a person obtains may depend on her family behavior: whether she is married or not, and the presence or absence of children. Those who marry early and get children may decide not to pursue lengthy education. But vice versa, a person's family behavior may depend on her educational behavior, whether she is in school or not (e.g., Marini, 1984). Being in school may delay family formation and getting children. In this example, family status is endogenous to schooling and schooling is similarly endogenous to family status. They mutually influence each other.

In the social sciences, many attempts have been made to assess the strengths and even possible directions of such mutual influences. These vary greatly in how successful they are.

A number of approaches have attempted to use cross-sectional data, with information about variables at one point in time, to determine the strength and direction of causation between them. One may obtain information on the amount of schooling and family status of say people who are 30 years old. One then tries, using advanced statistical techniques, to disentangle how the two mutually depend on each other. Such attempts suffer from the drawback that they do not take into account the sequencing of and the temporal relationships between the variables. They can hence not be considered particularly successful (see Alexander and Reilly, 1981).

An example may help. A woman may get pregnant at 18 years of age, after finishing high school. This may lead to a shorter subsequent education. But the shorter subsequent education did not influence the event of giving birth at 18 years of age. The expectation or intent of not obtaining additional education may have influenced whether to go through with a pregnancy at 18 years of age, but as noted above, an expectation about the future is not the same as the future. The shorter subsequent education may, however, shorten the time before the person has a second child, which in turn may delay further education. At 30 years of age, we may observe only the family status at that age, the number of children, and the education obtained so far. But unless one also collected data on the sequence of events as they unfolded over the life cycle, one cannot determine how childbirth influenced education and vice versa how education delayed or led to additional childbirths. Without a temporal relationship between values on two or more processes, mutual dependencies are hard if not impossible to assess (Petersen, 1995).

It is therefore widely recognized that such interdependencies are best studied by means of dynamic models using over-time data, where the sequence and types of transitions are studied as they occur over the life cycle. This was already pointed out by Lazarsfeld (1948).

In the context of the present example, with over-time data on several individuals, one can investigate how family status at 18 years of age influences schooling status at 19 years of age, and vice versa how schooling status at 18 years of age influences family status at 19 years of age. Suppose that family status has no impact on schooling status, so that marital status does not influence whether one goes to school or not in the next year. But suppose that schooling status has an effect on family status, so that it does matter whether you are in school or not for whether you get married or not in the next year. One would then say that schooling is an exogenous variable relative to family status. This is the same as saying that family status is endogenous to schooling status. If they both impact each other, then both are endogenous to each other. Having figured out what happens at 19 years of age, one can continue with analyzing the mutual influences of family and schooling status at 19 years of age on the same variables at 20 years of age, and so forth. One can sequentially unravel how the relationships between the variables evolve over time. Bentzel and Hansen

(1954) argued that mutual dependencies between two or more variables should be studied in such a manner.

There is an extensive statistical literature that addresses how to investigate which variables mutually influence each other, requiring access to over-time data as described above (Engle et al., 1983; Bergstrom, 1984; Petersen, 1995). Probably the best way to advance knowledge about which variables are endogenous and which are not is to collect careful data on sequences of event or variables (e.g., Wooldridge, 2010; Allison, 2013). No statistical technique can compensate for deficient data.

But no matter the kind of approach used or even favored, quantitative or more qualitative, the distinction between endogenous and exogenous variables is essential. Usually, there is some phenomenon in which we try to explain variations: the endogenous variable. Usually, there are some factors used to explain those variations: the exogenous variables.

Energy and Society

Abstract

The energy–society relationship is coevolutionary. On one hand, the material properties of energy inputs influence the structure and population size of a society and establish the parameters around, and expectations for, social and economic life. On the other hand, a physical entity is repositioned as an 'energy resource' only under specific technological and social conditions, and the evolution of energy systems represents a set of social choices shaped by political–economic (power) relations, cultural norms, and previous social decisions. The transition toward sustainable energy is as much a cultural and political project as it is a technological and economic one, and will (require societies to) reconfigure and reimagine sociotechnical structures and society–environment relations.

Introduction

The energy–society relationship is best described as coevolutionary and coproductive. On one hand, energy – i.e., the 'ability to do work' or 'capacity to influence the state of a system' (Smil, 2008) – is requisite for all human activities. Energy is derived from three primary sources: nuclear fusion reactions and subsequent radiant energy from the sun, gravitational force, and geothermal activity. These undergo a variety of transformations on Earth so that energy is also available in many secondary forms – e.g., stored in biomass and fossil fuels; flowing in water and wind (*see* Energy Flow Analysis). The quantity, quality, form, and spatiotemporal distribution of energy inputs into society establishes limitations on the population size and complexity of social systems and shapes the way in which institutions, conversion devices, and built infrastructure – or *sociotechnical metabolic pathways* – are organized in order to transfer energy between ecological and social systems (Luten, 1971; Cook, 1976; Smil, 2008). On the other hand, the types and quantity of energy used by a social system are structured by social norms, values, beliefs, knowledge, and previous social choices embedded in prevailing systems of energy provision (e.g., built infrastructure). Collective and individual energy choices are the means to achieve a certain kind of society and lifestyle, while social and technical conditions form the criteria by which specific energy resources are chosen and shape the way in which energy systems are incorporated into ongoing and new social functions (Lutzenhiser, 1993; Sovacool and Brown, 2007; van der Kroon et al., 2013).

In order to balance these 'energy deterministic' and 'socially constructed' perspectives on the energy–society relationship, this discussion is organized into two sections, which review well-established themes prominent in the academic literature. The first section explores the 'societal energetics' theme. Here, society is conceptualized as a "physical input-output system drawing material and energy from its environment, maintaining internal physical processes and dissipating wastes, emissions, and low-quality energy to the environment" (Haberl, 2006: 87). This section explores the relationship between social structure and energy use, as well as how new energy inputs (re)configure sociotechnical metabolic pathways. The second section explores the 'social construction of energy.' Here, the energy–society relationship is conceptualized as more than a physical process. This section explores the cultural and political economic processes that (re)position a physical entity as an energy input and, which shape sociotechnical metabolic pathways as well as desired energy services (end uses). As we unpack this relationship, we learn that the development of a sustainable energy system will include not only new resources and new technologies, but a new kind of society with fundamentally different attitudes toward, and ways of structuring and interacting with, the natural and built environment.

Societal Energetics

Humans are not *autotrophic* (self-nourishing) organisms and, like other *heterotrophs*, must redirect stocks and flows of energy in the environment toward basic physiological maintenance and growth. As such, available energy and more specifically edible biomass (i.e., stored chemical energy in plants and animals) is the primary physical mediator in the human–environment relationship (Cook, 1976). Energy provision is more efficient through collective rather than individual pursuits so that a social system might be conceived as a human strategy to extract energy from ecological systems (see Boehm, 1999). (A brief review of the first and second laws of thermodynamics brings precision to this notion: (1) energy available in a system is never created nor destroyed, only converted or transferred to another system; (2) all closed systems tend toward a state of increased entropy or thermodynamic equilibrium (less productive energy). Since energy is always available but degraded, it is more accurate to state that societies extract *productive energy*, otherwise known as *exergy* (Rosen, 2002), which is made available when high concentrations of pressure, temperature, or mass tend toward thermodynamic equilibrium (i.e., dissipate) within their environment. According to the 'maximum power principle,' those societies designed to dissipate these concentrations (maximize entropy) through productive social activities and physical infrastructure (embodied energy) are most likely to reproduce and grow (Odum and Odum, 1976; Rebane, 1995).) Energetic studies of social evolution reveal a correlation between the material properties of societal energy inputs and the size and structure of

a society. In other words, variations in energy inputs influence the organization of sociotechnical metabolic pathways and lead to very different kinds of societies in terms of size, structure, and energy services. For the sake of illustration, the following generalizes otherwise spatiotemporally diverse societies into three distinct regimes: hunter-gatherer societies, agrarian societies, and industrial societies (see Sieferle, 2001; Haberl, 2002; Goudsblom, 2012; Fischer-Kowalski et al., 2014).

Early hunter-gatherer societies relied primarily on recent photosynthetic activity as they foraged for edible plants and, when necessary, hunted animals to attain stored caloric energy (especially high-fat meat). The extent of daily and seasonal travel, as well as group population size, varied based on local spatiotemporal density of nutritional energy, which is typically higher in grassland biomes than in forest biomes. Societies living near, and supplementing terrestrial productivity with, marine ecosystems tended to be larger, more complex, and less nomadic. In fact, marine ecosystems were likely the first source of surplus energy. Salmon runs along the Pacific coast and Baleen whale migration in the Arctic Ocean are exemplary in this regard (Smil, 2008).

Hunting and gathering requires significant expenditures of energy, so that survival and growth is dependent on deliberate techniques to increase net energy gains. This was initially achieved in two ways. First, societies developed technologies and practices to store their food – e.g., freezing whale fat in underground permafrost shelters (Smil, 2008). Storage techniques liberated time spent hunting and gathering, allowing societies to spend their time in more interesting ways; a point we will return to later in the discussion. Second, humans physically preprocessed their food to improve the efficiency of the digestive process. Most notably, cracking, pounding, and grinding techniques were used to reduce the particle size of food intake and thereby expand the surface area exposed to digestive enzymes (Carmody and Wrangham, 2009).

These techniques notwithstanding, the energetic maturation of hunter-gather societies was marked by their ability to control fire for hunting and cooking. Cooking with heat further improves net energy gain from food by externalizing (using *exosomatic* energy for) the initiation of the digestive process, which (1) reduces the internal work (*endosomatic* energy) required for digestion and (2) improves the overall digestibility of useful energy from otherwise recalcitrant food (e.g., high-starch foods such as potatoes) (Carmody and Wrangham, 2009). Combined with the development and use of clay pots, fire also enabled the addition of soups to regular diets, which extracted nutritional value from otherwise inedible portions of a kill or a harvest. In addition, fire was used to direct large herds of animals to a more convenient location for hunting purposes and, later, smoke curing became a common way to preserve meat and fish where temperatures were not ideal for cold storage. More broadly speaking, the use of fire represents the first branch in fuel-mix diversity within social systems. Social groups now commanded two primary energy inputs – food (biomass with nutritional value for humans) and fuel (biomass with no nutritional value for humans) – and expanded the social functions requiring an energy input. To the latter point, the controlled burning of fire meant that humans no longer had to wait for the midday sun to find warmth and light. A controlled fire was also a focal point for social gathering, where ideas were shared and problems resolved. For these and other reasons, fire has in many ways come to symbolize the dawn of civilization (Goudsblom, 1992).

Generally speaking, hunter-gatherer societies are powered by, and structured around, 'uncontrolled solar energy' (Sieferle, 2001). Agrarian societies, in contrast, deliberately concentrate the flow of solar energy into edible biomass through two predominant systems: crop agriculture and pastoralism. Where precipitation and soil quality is sufficient, agrarian societies clear land of inedible phytomass (trees and grasses) to instead cultivate edible phytomass such as cereals, legumes, and tubers. While this activity reduces global net primary productivity (NPP) (because agroecosystems are less productive than the ecosystems they replace), it greatly increases useful energy density per unit area and the overall appropriation of local NPP by societies (Haberl, 2006). Where geophysical conditions are insufficient to support annual crop growth, such as in arid regions, solar energy is instead concentrated through pastoralist practices whereby the health and activity of large herds of animals is managed to ensure a steady conversion of inedible (lignocellulosic) biomass such as grasses into edible fat and proteins. Agrarian societies grew larger than foraging societies in large part because of higher yields of edible biomass; greater security of food supply; and the realization that increasing labor meant increasing returns on investment.

A sort of 'preindustrial' agrarian society began to emerge with organizational and technical innovations to agrarian energy production systems. An early example involves the concentration of otherwise diffuse sources of physical power in human and animal muscles – humans by force in slave nations or through coercion in feudal societies, and draught animals (horse, oxen) by domestication. These forces were multiplied efficiently using various combinations of harnesses, ropes, levers, pulleys, treadmills, and gears (Smil, 2008); technologies made increasingly available after the combined development of charcoal and controlled blast furnaces, which enabled, among other things, metalworking at large-scales. Preindustrial agrarian societies are also marked by greater fuel-mix diversity. Using what Smil (2010) calls new 'prime movers' – i.e., devices that capture and convert energy through a productive process – wind and water (*inaminate energy*) began to supplement human and animal muscles (*animate energy*). Windmills were used to pump water to clear or irrigate land and therefore expand the area that could be actively farmed. Turbines converted falling water into mechanical energy to process agricultural products (e.g., mill grain) at large scales. These new prime movers diversified energy inputs into societal functions, increased the overall energy appropriated from ecological systems for social use, and, in so doing, had profound impacts on where and how people (could) live (Pasqualetti, 2012).

The shift toward inanimate sources of energy initiated a trend toward the geographic separation of social activities. Agricultural communities expanded on flat and fertile soils producing surplus nutritional energy that was distributed to mill communities, which developed where kinetic energy in hydrological systems was concentrated at a waterfall. Trading hubs were established at calm natural bays along coastlines as well as the junction or mouth of major inland rivers, which also became strategic places. Specialization of social activities and

divergent attitudes toward space and time emerged in this new geoeconomy. Agricultural life was (is) very task-oriented and organized around seasonal variations of natural energy flows, while life in mill communities was (is) increasingly organized around clock time and shift work. Trading communities, through interaction with visitors (merchants), became increasingly cosmopolitan.

Wind and water energy systems also underpinned the emergence of more complex political economies and connected societies in new ways. The production of surplus goods using hydrological power combined with more extensive transport by sail were precursors to regional (and later global) markets. Otherwise distant social groups became increasingly connected through trade networks, and consumers began to value exotic goods by virtue of their foreign (locally scarce) nature. Furthermore, wind and water represent early 'energies of conquest' to the extent that they were the energetic basis of colonization (Nye, 2001). Indeed, early political maps were (re)drawn by those nations that managed their energy resources in a way that enabled the control of large populations over great distances, even in relatively small numbers; e.g., in the construction of naval infrastructure and weaponry. In many cases, the conquered society was forced into slavery, thereby reinvesting human energy (multiplication of smaller forces, discussed above) into the fitness and growth of the dominant society.

'Fossil energy' refers to subterranean concentrations of dead biomass in solid (coal), liquid (oil), and gaseous (natural gas) forms. These energy resources provided the quantity and form of inanimate energy that is requisite to an industrial society. The discovery of coal meant that manufacturing and metalworking activities could expand in size and spatial distribution even as forests were massively depleted of their wood. New prime movers were significant here as well: the invention of the steam engine highlights the mutually reinforcing nature of energy and technology from which industrial societies emerge and are maintained. Coal-powered steam engines slowly replaced falling water as the primary source of mechanical power. Since coal is a dense stock of energy that can be transported in bulk, manufacturing output became more reliable because it was no longer negatively impacted by periods of drought. Moreover, production centers could now be colocated with trade centers to maximize market exposure; indeed, the transition toward coal explains why many trading hubs became manufacturing centers (e.g., Pittsburgh, Pennsylvania) (Nye, 2001). (Prior to the introduction of coal and steam engines into manufacturing, production centers and trade centers were dislocated from each other because the river systems used to generate power (narrow, powerful) were not the same river systems that could be used for navigation (wide, calm).) Meanwhile, fossil energy systems allowed productive activities, and even entire cities, to expand in size and complexity even as they became increasingly disconnected from primary energy sources.

All inanimate energy systems – fossil energy systems chief among them – are more capital and less labor intensive. This underpins a number of profound transformations in social organization and the way societies perceive and behave toward their environment. A pipeline system that carries cooking gas to homes changes the social and household roles of women and children who traditionally gathered fuelwood (van der Kroon et al., 2013). A winter storm, once dreadful or inconvenient, can be perceived as delightful and oddly comforting with access to a natural gas furnace to keep warm. Capital intensive energy systems simultaneously reduce strain on muscles; increase leisure time; and contribute to periods of energy surplus. This combination has increased 'disposable' energy, which can be invested into nonproductive uses, some of which become new priorities and new economies – e.g., spending time and energy reducing one's golf handicap. As a corollary, the efficiency with which societies metabolize food decreases. So where high-fat foods were once an energetic necessity they are in some societies an energetic problem manifested as an obesity endemic. What's more, the capital intensive nature of modern energy systems has underpinned unprecedented social movements, especially within high-energy subgroups. Where endurance running to chase animals to exhaustion was once an investment of stored nutritional energy to improve hunting success (Smil, 2008: 139), many people now jog as a hobby or to maintain a body image. Where seasonal disruptions to agricultural output were once compensated with animal meat, diets can maintain diversity of vegetarian foods shipped over long distances in shorter time spans within refrigerated transport mediums. Access to cheap energy has significantly increased buying power, leading to pleasure shopping (high consumerism). The development of the internal combustion engine and modern transport systems based on liquid fuels underpins the desire for low-density living in North America, in contrast to high-density living within societies that developed with access to less flexible energy resources and transport systems (Pasqualetti and Brown, 2014).

The unique qualities of fossil energy resources have magnified dislocation between production and consumption. Because they are unevenly distributed and can be easily transported, societies are increasingly reliant on external rather than internal (domestic) sources of energy. This has social implications across scales. At the international scale, the uneven distribution of fossil energy resources strongly mediates the ways in which societies interact, underpinning 'resource wars' and at the same time reinforcing the strategic value of (international) sociopolitical institutions that facilitate amicable relations between producer and consumer nations such as treaties, trade agreements, and international agencies. Access to a natural endowment of energy resources is indeed no longer sufficient to explain the energetic evolution of a given society; Switzerland and Japan offer a case-in-point (Luten, 1971). At smaller scales, energy users have become disconnected from the direct environmental impacts of their energy choices, as their interaction with the actual ecological impacts of energy production is mediated through light switches, thermostats, and outlets. Because fossil energy resources are subterranean and higher in energy density than any other energy resource, the correlation between rising energy consumption and cultivated or deforested land area is drastically weakened. As such, a city can stay warm during winter while choosing to designate the surrounding forested area as a preservation area; the forest, once a source of fuelwood, can now be used for recreational purposes.

The development of electricity was also transformative, and especially to cities. As Nasaw (1992) explains, new kinds of

public spaces were made possible with the control of electric current. Electric lighting made possible imaginations of the 'city as a spectacle' through a welcoming blaze of 'big city lights,' and street lighting in suburban neighborhoods enabled a stronger sense of security, which encouraged 'pleasure walking.' Private space changed as well, increasingly decorated with bright rather than dark colors since the soot residue from gas lighting was no longer a concern (Nye, 2001). Electric motors could operate refrigerant technology, enabling localized cold storage while changing expectations around thermal comfort in the summer. Economies of scale in fossil energy extraction and hydrodam construction along with technological advances that control electric currents at the microscale in information and communication technology innovations have given rise to telecommuting (i.e., blurring the lines between work space and home space) and a culture of 24/7 connectivity or 'always-on-ness' (Spinney et al., 2012); new features of what might be called the 'information society.'

In sum, the process of reinvesting surplus energy into making land and industrial activity more productive is, for many theorists, the process through which societies are able to increase in size and complexity. As societies transition from labor to capital intensive energy systems they undergo profound changes to the way in which built and natural environment is organized, perceived, and engaged. Our prevailing energy infrastructure, land-use patterns, environmental ethics, and expectations and priorities related to energy use have been shaped by the use of dense, subterranean, flexible, and transportable stocks of fossilized energy. But we must be careful to avoid a sense of energy determinism here; although energy is the 'mother' and technology the 'father' of social growth and complexity and human–environment relations, social values are the 'midwife' (Rosa et al., 1988: 152).

The Social Construction of Energy

While energetic theories of society emphasize how forms of energy – as ability to do work – shape sociotechnical metabolic structures and social practices, social theories of energy focus on the social work (political, economic, cultural) that is done to turn a physical entity into an energy resource, as well as the social factors, which prioritize how physical work is expended and who benefits in the process of energy production, distribution, and use. From this perspective, the ways in which sociotechnical metabolic pathways are organized, and the types and quantity of energy that is used, involves a set of social choices. Stated differently, resources have no power outside of particular social and technical conditions. In addition to undermining energy determinism, this perspective challenges the 'energy ladder' model, which posits that energy choices are based on the energetic value of a given resource relative to the cost of acquisition. Surely, there is a noticeable trend within and between societies to convert energy into more useful forms – e.g., grass to meat; fuel into heat or electricity – as efficiently as possible. But economic choices are socially structured, meaning that noneconomic factors are important in understanding energy choices (Lutzenhiser, 1993). Indeed, deviations from the energy ladder model are prevalent. Despite access to gas and electricity, for example, wood and peat are still burned (for nostalgic reasons) in modern households and wood is in some cases preferred as a cooking fuel for a variety of traditional dishes (Taylor et al., 2011; van der Kroon et al., 2013). Under certain conditions raising animals for food results in a net energy loss, but as Smil (2008: 152) asks, how else could the provision of 'tasty' combinations of fat and protein be controlled? In other words, society does not follow a natural preordained order toward higher value fuels or more efficient energy systems, nor is energy exploited simply as a function of its existence. Energy exploitation, rather, is rooted in the cultural, political, and economic trajectories whereby (1) social meaning is attached to a physical entity, as well as a particular use of that entity; and (2) the skills, institutions, and built infrastructure through which an energy resource can be used (in particular ways) is established.

Not all individuals or cultures see the world the same way nor do all societies share the same goals. As such, different social groups will not equally rank the attributes of specific energy systems and the services that they provide. Firstly, since a decision to extract energy is necessarily a decision to alter the environment in some way, energy exploitation is directly related to social perceptions of and ethical positions toward the nonhuman world. As Nye (2001: 249) explains, the desire among early European settlers to make land more productive through intensive management was not shared by indigenous populations; this cultural difference rather than inherent technological ingenuity or access to coal underpinned European status as a 'high energy society' and dominance of the new world. Related to this point, Bell et al. (2005) identify a national local 'social gap' problem in the context of renewable energy development, whereby national level polls show strong support for renewable energy due to concerns related to climate change, while many local citizens are upset by, among other things, the way in which renewable energy infrastructure spoils the aesthetic qualities of local landscapes. Secondly, energy is requisite to all social activity and is therefore a means to a certain kind of society (Sovacool and Brown, 2007), so that energy production and distribution is wrapped up in ideas about social equality and social development. Although concentrated human labor certainly has energetic benefits, the misguided idea of inherent racial inferiority justified slavery toward this end; it was not some energetic imperative or a natural extension of having tapped the 'energies of conquest' (Nye, 2001). Huber (2013) demonstrates that (particular uses of) energy resources are intimately wrapped up in notions about life, liberty, and social organization; e.g., just-in-time delivery of goods, the single-family dwelling, and expectations around personal transport. Lizot (1977) suggests that energy demand is related to a cultural attitude toward work and ideas about what constitutes 'progress.' This is based on the observation that one group in close proximity to an animal-rich forest consumed less than half as much food energy and protein as a neighboring group, the former preferring instead to spend more time in leisure. Overall, these and other sociocultural factors help to explain why energy demands and energy systems between households and nations vary in space and time, even in the case where all other factors are equal (e.g., climate, resource endowments, technology, demographics).

In the same way that specific energy systems shape social and political movements, new social and political movements play

a role in reconfiguring energy systems. Those surrounding environmental values including localization of food diets and energy sustainability, which are driving investments into distributed renewable energy systems, as well as political movements aimed at democratic freedom or state control in the Middle East, which disrupt global supply chains of fossil fuels, are exemplary in this regard. At the same time, energy choices are both constrained and enabled by past social choices, which underpin prevailing institutional and technical contexts. Nye (2001) suggests that an industrial revolution could emerge only in the context of an *industrious* revolution among certain (members of) societies, whereby more members of the household were driven toward paid labor by commercial incentives, and consumer tastes were enhanced due to rising purchasing power. Another example comes from attempts at large-scale rural electrification programs in developing nations, many of which failed because rural citizens in these countries could not afford the appliances necessary to utilize electricity, nor had they developed a set of cultural practices that necessitated or valued electricity consumption in the first place (Taylor, 2005).

Shove and Walker (2010) point out that energy might best be conceived as one ingredient in an individual 'performance,' which affirms or resists many of the sociocultural conventions discussed above. They take showering as an example: ideas about 'freshness' and how it relates to social acceptability or social status, combined with the interaction of material elements such as shampoo and indoor plumbing at spaces dedicated for bathing, perpetuate energy-intensive hygiene. From this perspective, energy use is as much involved in a struggle for social fitness and legitimacy as it is a matter of economic efficiency. The diffusion of particular energy resources or technologies, then, is the diffusion of 'multiple, multisited' social practices (Nicholls and Strengers, 2014). What's more, the process of normalization of these practices, as well as the resources and systems through which they are supplied, is rapid. The peculiar affordances of fossil energy systems, for example, ranging from greater convenience in basic provisions (e.g., high-yield food production; internal room temperature of 20 °C) to expanded access to luxury (e.g., timely exotic travel and year-round vegetarian diets), are perceived by many as imperative to social and economic life even though these features are unique to what Shaffer (2009) calls 'hydrocarbon man,' an era equivalent to only 0.01% of humanity's 'terrestrial tenure' (Cook, 1976). This coembedded and mutually reinforcing relationship between social institutions and individual practices with energy systems means that deconstructing prevailing fuel-mixes, sociotechnical metabolic pathways, and use profiles is a sluggish process (Unruh, 2000). This is true despite potential to achieve gains in energy efficiency; e.g., uptake of agricultural practices was delayed in places where foraging yields were sufficient to satisfy lifestyle demands (Smil, 2008) and slave labor systems delayed uptake of steam power in the southern U.S. agricultural systems despite clear signs that steam power was beginning to rearrange the competitive landscape (Nye, 2001). Currently, although renewable energy is socially accepted in principal prevailing livelihood strategies, built and natural environments, and vested political economic interests (e.g., social status) that are wrapped up into prevailing energy systems are recalcitrant. Furthermore, there are clear tensions between proconservation values and the desire for convenience, comfort, and social status that comes with energy consumption (Lutzenhiser, 1993). These inconsistencies underpin the notion that renewable energy is unlikely to support the 'modern lifestyle' (Bryce, 2010; Trainer, 2013). Since the modern lifestyle is unlikely to be voluntarily redefined, the argument goes, renewable energy will never receive political support unless of course a geological imperative forces such a change. To the latter point, it is important to consider the fact that energy demands related to the construction of a 'modern lifestyle' in less developed countries are now driving the demand curve for energy, and have contributed to nearly 80% of the global demand growth for fossil resources in the last decade (Simon, 2005; IEA, 2012).

With all of this in mind, theories are divided on how to encourage societal change in terms of energy production and consumption. Three approaches are common and are most effective when targeted or creatively combined: (1) appeals to individual costs and benefits; (2) appeals to intrinsic values, as when renewable energy is connected to notions of 'energy democracy' and 'the health of the community/public'; or (3) by deconstructing prevailing norms and their supportive infrastructure and institutions and replacing them with new ones, such as redefining what thermal 'comfort' means (Rosa et al., 1988; Moloney et al., 2010; Nicholls and Strengers, 2014). Coercion through command-and-control (tax) or market mechanisms (pricing) is also an option. Responses to price signals are differential based on willingness and ability to pay. This approach also comes with significant ethical baggage because it restricts access to what is perceived to be, or at least rhetorically framed as, a social imperative – i.e., cheap (fossil) energy – and it will certainly disproportionately burden low-income groups. Another solution is to focus on improvements to the efficiency of energy production, distribution, and consumption technologies, which can, in theory, dramatically reduce energy demands without a change in lifestyle. Critics of this approach are quick to invoke Jevons' Paradox (see Sorman and Giampietro, 2013), which posits that improvements in energy efficiency, by themselves, do not lead to absolute reductions of energy use because people tend to enroll surplus energy into new services (e.g., outdoor garden lighting) or into enhancing existing ones (e.g., when heating systems are made more efficient, internal temperature is increased).

Conclusion

Energy is a physical entity that underpins all societal functions. The quality, quantity, form, spatial distribution and timing of energy availability, and the sociotechnical metabolic pathways through which they are recovered sets parameters around what kinds of societies are possible in terms of structure (size, complexity, political economic organization) as well as culture (livelihoods and lifestyles). To this point, terms such as 'hydrocarbon man' and 'fossil capitalism' are deliberatively provocative and meant to elicit the notion that fossil fuels are embodied at the individual and the collective level. But this embodiment is not inevitable, nor the result of a natural or preordained progression along an 'energy ladder.' The types of physical entities that become an energy resource, the way in which systems of energy provision are organized, and the use

profiles toward which they are oriented are all social network effects. In other words, they are material expressions of a dynamic interplay between common collective goals, accepted forms of interpersonal interaction, identity formation, power imbalances, knowledge, attitudes toward the nonhuman world, and prior social decisions. As such, societies and energy systems are coproductive, and they evolve together in nonlinear and spatiotemporally heterogeneous ways.

Growing concerns around current systems of energy provision related to resource availability and environmental impact, combined with key technological advancements, have redirected policy and industry attention toward unconventional fossil fuels (e.g., shale energy and oil sands) as well as renewable energy resources. What we have learned above is that these energy transitions are not natural progressions, nor are they simply a change in fuel-mix. They are cultural as well as political projects, which ultimately (require societies to) reconfigure sociotechnical structures, society–environment relations, everyday routines, and the social institutions and norms by which all of these are structured. Debates about our collective energy future are not only conversations about how to redesign infrastructure or economic systems, or about which technologies and resources are best; they are also about what kind of a society we envision and our individual roles therein.

Abstract

This article reviews anthropological research on energy dating back to the 1940s. Three generations of research are identified and explored: the first was Leslie White's pathbreaking effort in the 1940s and 1950s to rethink models of cultural evolution through the lens of energy use. Then, in the 1970s, a second generation of anthropological research took shape in response to the global oil shocks and the beginning of serious political debates over the need for transition to renewable energy resources. Those conversations were largely silenced by a political recommitment to carbon and nuclear fuel across the world in the 1980s. However, in the past several years, a third generation of anthropological research has rapidly developed, spurred by mounting evidence of anthropogenic climate change and its impacts of human and nonhuman life across the world.

As viewed from the perspective of rapidly accumulating anthropological research on energy impacts (e.g., Crate and Nuttall, 2009) and energy transition (e.g., Howe, 2011) across the world, the anthropology of energy would seem to be a research area of rather recent and specific vintage, a response above all to growing scientific and political attention to anthropogenic climate change. Yet energy is a topic that has long been addressed in social–cultural anthropology, even if largely outside of mainstream research trends. By the author's count, the lively research field that has formed in the past decade is no less than the third generation of the anthropology of energy. In this article, the author reviews past and present anthropological research on energic forces and forms and offer some guarded speculation about where the field will head in the coming decade.

Energy and Cultural Evolution

The anthropology of energy's first generation was defined foremost by the work of Leslie White, a maverick thinker who granted energy a prominent place in his efforts to resurrect evolutionary theory in American anthropology (1949, 1959). For White, energy was not just one research topic among others; it was the conceptual key to understanding everything about human life and history. In what is arguably his most influential work, '*Energy and the Evolution of Culture*,' he outlined a literally universal theory: "Everything in the universe may be described in terms of energy. Galaxies, stars, molecules and atoms may be regarded as organizations of energy. Living organisms may be looked upon as engines which operate by means of energy derived directly or indirectly from the sun. The civilizations or cultures of mankind, also, may be regarded as a form or organization of energy" (1943: p. 335). White's key equation was that "cultural development varies directly as the amount of energy per capita per year harnessed and put to work" (p. 338). Thus, at the beginning of cultural history, with only the energy of its bodies with which to operate, humanity's cultural development remained at a very low level. To satisfy needs and to improve capabilities, both physical and intellectual, humanity sought to harness new sources of energy, first in the domestication of animals and plants, increasing "tremendously the amount of energy per capita available for culture-building" (p. 343). But after several thousand years of steady improvement, humanity once again plateaued until the advancements of the eighteenth and nineteenth centuries allowed the widespread harnessing of fuel and the invention of engines. Fuel and engines were the technological-cum-sociological basis of modern civilization, White said, and the source of all its great cultural leaps forward from machinery to the arts.

Although in many respects a teleological narrative of cultural advancement, White also emphasized a dialectical process. The social system optimalized for a given energy regime typically resisted new technologies designed to harness even greater magnitudes of energy. So when "cultural advance" ceased under a given energy regime, "it can be renewed only by tapping some new source of energy and by harnessing it in sufficient magnitude to burst asunder the social system which binds it" (p. 348). Thus, the fuel regime exploded the social apparatus of the agricultural regime in the modernization of society, a story that political economy interpreted as the struggle between two political orders (capitalism and feudalism). Encrypted here is the kernel of an idea that had great, but mostly undeveloped, critical potential: the notion that modern capitalist society was a fuel society to its core; its achievements were fundamentally predicated on fuel consumption such that rampant consumption had become archetypal throughout its culture. It is possible that White did not pursue this avenue of cultural critique because he felt the fuel regime was nearing its end anyway. He wrote of peak oil and peak coal, of dwindling reserves of fuel for a world demanding more and more energy. A committed but closeted socialist, White doubtless found his energy theory a reassuring rationale for impending revolution. He invoked the Second Law of Thermodynamics frequently in his writings to establish a Manichean struggle between the dissipation and concentration of energy in the universe, history, and culture (e.g., "All life is a struggle for free energy," 1987: p. 118). Life being, in his view, the fundamental struggle to concentrate energy against entropy, it could not cease with the dimming of fuel. Instead, new energies would eventually be harnessed and new social systems and cultural advancements would accrete around them.

White's sense of an energic revolution in the making deserves some context. In the late 1930s, successful experiments in nuclear fission set off a great deal of scientific and popular speculation about what a possible several million-fold increase in the energy at humanity's disposal would mean for all aspects of social life (see, e.g., O'Neill, 1940). Then, just months before the publication of White's landmark 1943 article, Enrico Fermi and his Manhattan Project team accomplished, although in secret, the first self-sustaining nuclear chain reaction – the pioneering controlled operationalization of nuclear energy that would pave the way toward 'the atomic age.' White noted the terrific potentiality of nuclear energy, "To be able to harness sub-atomic energy would, without a doubt, create a civilization surpassing sober imagination of today" (1943: p. 351), although he ultimately seemed more attracted to the possibility that the sun would become "directly our chief source of power in the future" (1943: p. 351).

Although prescient in these and other ways, White probably was as much an obstacle to future anthropological research on energy as an inspiration. His politics and personality won him a few friends but many more enemies, enemies who succeeded in isolating him and minimizing his work for many productive years. Not only did his universalist model stand in sharp contract to the Boasian historicism and individualism that dominated American anthropology of the 1940s and 1950s, but also White compounded this contrast with a strident insistence that the evolutionist thinking of figures like Lewis Henry Morgan and Edward B. Tylor was more coherent and theoretically superior to the work of Boas. It was many years before some rapprochement could be found between White and the Boasians, by which time other, less controversial figures like Julian Steward, Marshall Sahlins, and Elman Service had become more central to the movement that had come to be known as 'cultural materialism,' pushing White's thermodynamic and energetic focus into the shadows of mainstream social–cultural anthropology.

Politics of Energy Development and the Culture of Energy Experts

There is thus less genealogy than one might expect between the first generation of anthropological interest in energy and the second generation, which emerged in the 1970s and 1980s. Some Whitean influence remained, particularly through the networks of Michigan anthropology (see, e.g., Adams, 1975; Rappaport, 1975) but there were concerns as to how to develop White's energy theory further. In his 1977 Presidential Address to the American Anthropological Association, Richard Adams recalled his tutelage under White and the problems that arose from importing physical and chemical conceptualizations of energy into social analysis, "Basically, we relied on the first and second laws of thermodynamics and followed the example of community ecologists. But the fact that the second law was applicable only to closed systems posed substantial barriers to its use in analyzing human societies. They were, after all, clearly open systems. I think the dilatory development of energy study in social anthropology is in part the result of an inadequate theoretical basis provided by physics and chemistry" (1978: p. 298). Adams did not view this problem as insurmountable, seeing great promise, for example, in the chemist Ilya Prigogine's "foundation for an understanding of thermodynamic open systems" (p. 302), but he noted that road ahead required a shift to the "holistic study of larger societies" (p. 301) for which, in his judgment, anthropological theory was as yet poorly equipped. Adams's address ended with a rousing and once again prescient call for anthropologists to take a more active role in the critical investigation of the magnitudes and sources of energy flow with an ultimate aim "to develop more direct dependence on solar energy and to reduce both the use of nonrenewable energy forms and the derangement of the natural ecological processes that construct the energy forms we need for our own nutrition and that of other species" (p. 307).

Yet, by and large, this call was not taken up immediately. Second-generation anthropologists of energy typically did stand in a critical relationship to the energy forms and norms of the developed world. But they were significantly less interested in advancing energetic and thermodynamic cultural theory than they were interested in highlighting the cultural and social impacts of energy development for indigenous peoples (Nordstrom et al., 1977) especially in terms of nuclear power (Robbins, 1980), uranium mining (Robbins, 1984), and oil extraction (Kruse et al., 1982; Jorgensen, 1990). The second generation thus drew energy into important wider debates over the rights of indigenous communities, environmental impacts and resource exploitation, debates that remain central features of the anthropology of energy today (e.g., Love and Garwood, 2011; Powell, 2010; Sawyer, 2004; Sawyer and Gomez, 2012). But, at the same time, much as Adams feared, the mainstream discipline's interest in the topic of energy remained 'dilatory.' The AAA flagship journal, *American Anthropologist*, for example, published scarcely any energy-related research after the mid-1970s. In part, this gap can be attributed to the 'applied' character of many second-generation projects that were designed foremost to help improve relationships among indigenous groups, corporations, and governments as regarded energy development (see, e.g., Jorgensen et al., 1978). But it also expressed the sense of theoretical impasse to which Adams had alluded as well as the progressive retreat from anthropological holism that was occasioned by growing subspecialization of anthropological research and the waning capacity of the subfields to communicate and collaborate effectively with each other.

An important exception to this trend was the work of Laura Nader, whose participation in the late 1970s in the US National Academy of Science's Committee on Nuclear and Alternative Energy Systems (CONAES) served as an inspiration to Adams as to what anthropologists might be capable of accomplishing (1978: p. 307). Through her research on behalf of CONAES, Nader became interested in the contribution of worldviews, both popular and scientific, to the rejection of ideas of energy conservation and energy transition (Nader and Beckerman, 1978). As the first anthropologist to research the energy policy community and energy scientists, Nader became both fascinated and deeply disturbed by "the culture of energy experts" (2004: p. 775). She saw energy policy as "grounded in fear of deleterious change in life-styles and options" despite considerable evidence of "the very wide range of choices of

life-styles that is available in any plausible energy future" (Nader, 2010: p. 241). Energy science meanwhile was plagued by an "inevitability syndrome" (2004: p. 775) that resisted models not predicated upon ever-increasing resource use and energy expenditure:

> Also striking was the omnipresent model of unilinear development (a concept that anthropologists had left in the dust decades earlier), with little general understanding of macro-processes. For example, the recognition that civilizations arise but that they also collapse was missing from the thinking about the present. Prevalent was the nineteenth century belief that technological progress was equivalent to social progress. In such a progressivist frame science too could only rise and not fall or wane. Furthermore, the possibility that experts might be part of the problem was novel to the expert who thought that he stood outside of the problem. (2004: p. 776)

Nader ended up laying much blame at the foot of the specialization and hierarchization of scientific communities in which 'standardization and conformity' ruled the day (ibid) and prevented much needed creative thinking about energy futures. Among anthropologists, Nader remains the only scholar to have researched the expert imagination of energy futures in such depth. Her work also paved the way for more recent ethnographies of energy experts (Mason and Stoilkova, 2012) and for political anthropologies of carbon (Coronil, 1997) and nuclear (Gusterson, 1996; Masco, 2006) statecraft.

If there is a lesson to be drawn from the timing of the first two generations of anthropological research to energy it is that they have accompanied vulnerable or transitional moments in dominant regimes of 'energopower' (Boyer, 2011). In White's case, his positioning of energy as the key to understanding all human culture (and indeed all existence), accompanied the nuclear energy revolution and its new magnitudes of creative and destructive power. In case of the second generation, the context was what Nader termed "the energy decade" of the 1970s. Beginning with the oil shocks of 1973 (that signaled the end of a certain phase of Western imperial control over carbon fuel resources, particularly in the Middle East) and followed by a short-lived political willingness to explore alternative energy sources, fissures and tremors spread in the energopolitical apparatus that attracted anthropological attention. The political recommitment to carbon and nuclear energy across the industrialized world in the 1980s blunted the aspirations and urgency of energy research in anthropology as elsewhere in the human sciences. Indeed, between the mid-1980s and the mid-2000s, anthropological research on energy seemed to go into a kind of hiatus (see, however, Dawson, 1992; Coronil, 1997), before displaying signs of renaissance (Henning, 2005; Love, 2008; Mason, 2007; Sawyer, 2004; Wilhite, 2005). Over the past several years, in response to growing public and political attention to questions of climate change and energy transition, a mounting body of intriguing case studies has begun to generate more profound theoretical challenges (e.g., Reyna and Behrends, 2008; Sawyer, 2007; Winther, 2008). Some 70 years after White's landmark paper, it seems as though energy has at long last become a subject worthy of serious attention in mainstream social–cultural anthropology.

Energy Anthropology in the Era of Anthropogenic Climate Change

This inevitably raises the question as to where the anthropology of energy is headed next. Since, in its third generation, the anthropology of energy is expanding and subspecializing rapidly, it is likely that it will have not one but several paths ahead of it. The author comments here briefly on three that seem particularly promising:

1. Critical political and environmental ethnography of carbon fuel and its impacts. As the demands of human civilization and the expansion of human population increasingly impact the planetary ecology, one finds anthropology sharpening its critical attention to carbon fuel economies and their social and environmental impacts (see, e.g., Behrends et al., 2011; McNeish and Logan, 2012). This literature aims at surfacing the political-economic importance of apparatuses of carbon fuel extraction and challenging common Northern models of resource management (in which constant growth of demand and supply is not only tolerated but actively encouraged). Scholars are investigating how projects of carbon fuel development can be at once a blessing and a curse to communities across the world, not only attracting new wealth but also cultivating forms of social exclusion and inequality alongside environmental toxicity. Although attentive to contemporary dimensions of resource demand and contention, this literature is deeply connected to earlier generations of energy anthropology, especially to the second generation's interest in the politics and impacts of energy extraction in indigenous communities and to White's inchoate critique of the social forms of fuel society.
2. Studies of the social formation of climatological and energic expertise. At the intersection of energy anthropology, the anthropology of knowledge, and anthropological science and technology studies, we find very vibrant conversations emerging over the social formation of climatological (e.g., Hastrup, 2012) and energic (e.g., Mason and Stoilkova, 2012) expertise and the processes through which forms of energy and environmental authority (or, 'ecoauthority,' see Howe, forthcoming) are constituted and defended. What animates this area of research is not, for example, skepticism regarding the facticity of climate change so much as recognition that theories of climate change, like other modes of expert knowledge, operate in complex and often competitive fields of epistemic authorization. Scholars in this research area thus argue we need to better understand how climatological and energic knowledges originate; in what kinds of expert communities, institutions, and practices; how and why some models thrive and others fail; and how expert models are received, challenged, and/or elaborated by other (e.g., political and economic) authorities and by publics. Like the resource and fuel studies noted above, this is a research area that is both highly innovative (especially in terms of its leveraging of analytic methods drawn from the anthropology of knowledge and STS) and also extensional of earlier research, particularly Nader's initial spadework on the culture of energy experts, in its effort to illuminate

dominant and emergent forms of expertise at the juncture of energy and the environment.

3. Critical reevaluation of anthropological models of political power through the lens of energic forces and infrastructures. Finally, in the past few years, it has seemed increasingly urgent to rethink, in a more fundamental way, anthropological models of political power through what the author has termed 'energopower,' power seen through the twin analytics of electricity and fuel (Boyer, 2011, forthcoming; Rogers, forthcoming). Although this line of thinking certainly is connected to White's, it does not seek to simply import the truth propositions of the physical sciences into anthropology, although for somewhat different reasons than the concerns raised by Adams. Anthropology remains necessarily attentive to the mediation of truth claims such that it cannot ignore the social and historical contingencies of even mathematical and physical sciences. Thus, energopolitical analysis is not premised upon the universal truth of energic theory. Rather, it utilizes energy as lens through which to bridge and balance historical, material, and political dimensions of power. Topically, this research area communicates actively with the broader 'ontological turn' in the human sciences and with rising consideration of energoenvironmental infrastructures like electricity grids, pipelines, and water and waste systems. The theoretical inspiration for this move to rethink political power through the lens of energic forces and infrastructures comes most directly from engaging the work of scholars such as Timothy Mitchell (2009, 2011) and Hermann Scheer (2004). Mitchell revealed how twentieth-century Keynesian social democracy was enabled and later disabled by changing infrastructures of carbon energy. Scheer meanwhile analyzed how the longer energy supply chains materially intrinsic to carbon and nuclear fuel systems supported centralized modes of political authority and governance and theorized that the shorter supply chains of solar energy could generate new democratic political possibilities. Anthropological research on energopower and energopolitics is interested in both expanding the range of ethnographic case studies that discuss these entanglements of energic and political powers, and also in developing more general theoretical propositions. The hope is that both can help the human sciences to more adequately criticize our current patterns of energy flow and use (as they are clearly fomenting ecological crisis), and to imagine and advocate for new and more responsible institutions.

Abstract

Energy is a key concept for understanding the functioning of any biophysical system. In physics, energy is defined as the ability to do work. The physical notion of energy encompasses mechanical (potential and kinetic) energy, radiant energy, chemical energy, heat, electric energy, and nuclear energy. Biophysical structures of society are intrinsically linked with the biosphere through the energy flows required for their growth, sustenance, and functioning. Socioeconomic energy flows include food for humans and livestock as well as all the energy required for artifacts (infrastructures and machinery). Energy balances published by statistical offices trace the flow of energy through an economy. They include data on primary energy, energy conversion processes, final energy, and sometimes useful energy, usually in sectoral disaggregation. These energy balances include 'technical energy,' i.e., energy used in machinery and artifacts but neither food and feed required to nourish humans and livestock nor their physical work. More inclusive methods of energy flow analysis can be used to derive a comprehensive picture of society's energetic metabolism. This is particularly important when looking at socioecological transitions, e.g., from agrarian to industrial society due to the large importance of food, feed, and physical work in preindustrial societies. In addition to measuring the energy throughput of societies, methods exist to evaluate the efficiency with which energy is gained and used. For example, the amount of energy society needs to invest per unit of energy obtained from a particular source – its 'energy return on investment' – is a key characteristic of any primary energy source. This article explains some basics of energetics and discusses methods to account for energy use (conventional energy balances, comprehensive energy flow analysis) as well as the efficiency of energy provision and energy use.

Energy is an abstract, multifaceted notion. It is of paramount importance for the functioning of all biophysical systems (Smil, 1991), including the biosphere, and of course also the biophysical structures of social systems (Fischer-Kowalski, 1998). Energy flows between ecosystems and socioeconomic systems are an important part of the socioeconomic metabolism. Energy is of pivotal importance for sustainability because many sustainability problems of human societies are strongly related with the quantity and quality of energy used (Haas et al., 2008). Energy is an indispensable economic resource because almost all technologies used in production, transport, distribution, and consumption activities are somehow related with the availability and conversion of energy (Warr and Ayres, 2012). There is a long-standing, highly controversial discussion in the social sciences to what extent energy can be used to explain social phenomena, ranging from outright denial of any explanatory power of energy to the assumption that energy were one of the most important drivers of socioeconomic change (Martinez-Alier, 1987).

The purpose of this article is to discuss how energy flows in societies can be measured, accounted for, and analyzed. It discusses several perspectives and indicators that have been proposed and used to account for socioeconomic energy use.

What Is Energy?

The notion of energy as used in physics – which is how the term will be used here – defines energy as the ability to do work, i.e., to exert a defined amount of force over a defined distance. This abstract definition covers a large range of phenomena:

- Mechanical energy (kinetic and potential energy): the energy related to the movement or location of objects with a defined mass;
- Chemical energy: the energy stored in chemical compounds and released in chemical reactions, e.g., in combustion;
- Heat energy: the energy related to the temperature of physical objects;
- Electric energy: the energy related to a current of electrons through a conductor if an electric potential is applied;
- Radiant energy: the energy in electromagnetic radiation such as sunlight or X-rays; and
- Nuclear energy: the energy in the nuclei of atoms that can be released by fusion or fission of nuclei.

Energy Units

All these different kinds of energy can be measured in the same units. Unfortunately, there is a plethora of units used to measure energy. The SI unit is the joule (J). One joule is defined as a force of one newton (N) exerted over a distance of one meter (m). Because 1 N is a very small amount of force, 1 J is also a very small amount of energy. In almost all practical contexts, one will be concerned with multiples such as kilojoule (1 kJ = 10^3 J), megajoule (1 MJ = 10^6 J), gigajoule (1 GJ = 10^9 J), terajoule (1 TJ = 10^{12} J), petajoule (1 PJ = 10^{15} J), and exajoule (1 EJ = 10^{18} J). For example, humanity's current primary energy use is a bit over 500 exajoules per year (EJ y^{-1}). Unfortunately, a large number of units is commonly used for energy. Table 1 gives information on some often-used units and provides conversion factors for converting those into joules.

Thermodynamics

One of the important characteristics of energy is that it cannot be destroyed (which, strictly speaking, also means that the

Table 1 Some common energy units

Abbreviation	*Unit*	*Conversion to Joules*
kWh	Kilowatt-hour	1 kWh = 3.6 MJ
Cal	Calorie[a]	1 cal = 4.186 8 J
Btu	British thermal unit	1 Btu = 1.055 kJ
quad	Quadrillion Btu	1 quad = 10^{15} Btu = 1.055 EJ
toe	Tons of oil equivalent	1 toe = 41.868 GJ[b]
tce	Tons of coal equivalent	1 tce = 29.3 GJ[b]

[a]Note that 'food calories' always refer to kilocalories. 1 kcal = 1000 cal (10^3 cal).
[b]Indicative value: different conventions exist. If possible, always check for conversion factor assumed.

commonly used phrase 'energy consumption' is flawed). Physicists have formulated this as the first law of thermodynamics, which states that in a closed system, the total amount of energy is constant.

That all kinds of energy can be expressed in the same units, i.e., are on a certain level equivalent, does not imply that they were equal in terms of quality. The decisive question here is concerned with energy conversions, i.e., under which conditions one kind of energy can be converted into another. This is governed by the second law of thermodynamics, sometimes also called the entropy law. It states that in a closed system, energy conversions can only occur if entropy increases. Entropy is related with order: with rising entropy, order decreases. Consider the kinetic (mechanical) energy of a moving object, e.g., a falling stone, all atoms in the stone move in the same direction, i.e., their order is very high (low entropy). When the stone hits the ground, the kinetic energy is released, usually resulting in a deformation of the surface. The kinetic energy results in a deformation, i.e., a change in the potential energy of the surface material. In addition, during the impact, heat was released due to friction. If this happens in a closed system, the total energy is of course constant (first law of thermodynamics) but the entropy has increased (second law) because some of the highly ordered energy (kinetic energy) was converted to a very low-order energy, heat, i.e., the random movement of atoms and molecules within the stone, the surface, and the air above them; and perhaps some ordered structures were also destroyed during the impact.

What is meant by measuring all different kinds of energy in one unit, therefore, is that they are equivalent with respect to the lowest quality energy in the list, i.e., heat, into which all other kinds of energy can be converted without loss. In other words, what is being measured is the 'heat equivalent' or enthalpy. Because of the quality differences of different kinds of energy, it makes sense to introduce a second measure to characterize energy flows, which is exergy. Exergy is a measure of energy quality, i.e., the fraction of an energy flow that could be converted into mechanical energy, i.e., the highest quality energy. For heat, exergy depends on the temperature difference of a physical object compared to its environment. At ambient temperature, exergy is zero because no temperature flow exists that could be used to generate mechanical energy. The higher the temperature difference, the larger the temperature flow, and hence also the fraction of the heat energy that could (theoretically) be converted to mechanical energy.

Power

Another important distinction is that between energy and power. Energy refers to a defined amount of work performed, regardless of the time used to do so. Whenever energy is flowing or converted, this happens at a certain rate, i.e., a certain amount of energy is converted per unit of time. The physical notion to characterize this is power, defined as energy flowing per unit of time. The SI unit of power is the watt (W): one watt is defined as one joule per second ($1\,\mathrm{W} = 1\,\mathrm{J\,s^{-1}}$). If an energy flow of 1 W persists for 1 h (3600 s), the total energy flow amounts to 1 W h.

Energy Flows in the Biosphere

The whole biosphere can be described as a giant system of material flows, materially closed but driven by a continuous influx of energy from the sun (as well as some geothermal energy from the hot interior of the earth). The influx of radiant energy from the sun drives the earth's climate system, including all atmospheric processes (evaporation of water, cloud formation, wind, etc.), as well as almost all life processes (except for chemosynthetic organisms, e.g., deep-sea bacteria living near hydrothermal vents; Odum, 1971).

The basic process capturing solar energy and turning it into chemical energy available for all living organisms is photosynthesis. Through photosynthesis, plants transform inorganic inputs (carbon, water, nitrogen, phosphorous, etc.) into the myriads of different energy-rich organic materials of which all organisms consist. This process is denoted as 'primary production' and can be described using indicators such as gross and net primary production. The latter is abbreviated as NPP and is defined as the total amount of carbon fixed through photosynthesis (i.e., gross primary production), net of the plant's own energy demand.

Organisms capable of photosynthesis are denoted as 'autotrophic,' i.e., they can feed themselves from inorganic supplies. All other organisms – animals, fungi, and many microorganisms – are called 'heterotrophic' because their energy supply depends on the intake of organic materials from either living or dead organisms. An important branch of ecology (often called synecology or ecosystem ecology) is concerned with analyzing the flow of trophic energy through ecosystems, using distinctions such as herbivores (animals eating plants) or carnivores (animals eating other animals, which may be subdivided into several levels, depending on their prey) and analyzing the structure of food chains or food webs, as well as the processes of primary production and nutrient cycling in ecosystems.

Through hunting, gathering, cropping, livestock rearing, or forestry, humans are able to tap into this flow of trophic energy (Boyden, 1992), thereby appropriating a fraction of the NPP for their purposes (*see* Land Change: The Merger of Land Cover and Land use Dynamics; Land Use Indicators). Since the Neolithic revolution, humans actively manage or 'colonize' (Fischer-Kowalski and Haberl, 1993) ecosystems, thereby affecting many important patterns and processes in ecosystems, including soil, hydrology, the species composition of vegetation, nutrient and carbon cycles, and many more, in order to be able to harness the productivity of ecosystems for human purposes.

Energy is also of paramount importance at the level of the individual organism. The metabolism of any organism requires a continuous flux of energy, either as radiant energy or chemical energy in the form of food. All the intricate biochemical reactions within an organism critically depend on this energy supply for growth, maintenance of body functions, including their ability to do work, and reproduction. This of course also applies to the food supply of humans and livestock, and hence to socioeconomic metabolism.

Energy Flows in Socioeconomic Systems

Energy in Socioeconomic Metabolism

The concept of socioeconomic metabolism includes all stocks and flows of materials, energy, or defined substances (e.g., carbon) related to a society (*see* Energy and Society). This concept entails defining biophysical structures of society (physical stocks, usually thought to include human bodies, livestock, and artifacts) that require a continuous inflow of materials and energy to be reproduced and to function the way they do (Ayres and Simonis, 1994; Fischer-Kowalski, 1998).

This physical inflow is either taken from the biosphere (resource extraction) or imported from other socioeconomic systems. During production and consumption processes, materials are transformed from raw materials to interim products (often in many stages), final products, and eventually wastes and emissions that are generated throughout the production chain and at the end of the lifetime of products. A considerable fraction all materials used by a society ends up as infrastructures, including not only transport or manufacturing infrastructures but also housing and commercial buildings.

All these processes require energy, be it in the form of physical work of humans or livestock or produced through various kinds of machinery, heat, and chemical energy. Indeed, a considerable fraction of the materials that make up a modern society's metabolism are used for energy supply, e.g., coal, petroleum, natural gas, or biomass, which is used not only for combustion but also as food supply for humans and livestock. Use of materials and energy is therefore closely linked: Production processes and the use of products and infrastructures require energy (e.g., houses need to be heated, cooled, and lighted), but causality also runs in the opposite direction: available infrastructures increase the attractiveness of certain technologies, e.g., the more roads there are the higher the utility of a car.

Conventional Energy Statistics and Balances

Nutrition of humans and livestock is a relevant energy conversion process even under industrialized conditions but even more so in agrarian societies. Nevertheless, modern conventions for compiling energy statistics and energy balances for national economies exclude these biological energy flows and report only energy used in artifacts, i.e., in technical structures such as motors, power plants, furnaces, and boilers (IFIAS, 1974).

The notion of 'energy statistics' refers to any collation of energy data. Such data are usually collected by statistical offices and often presented in a multitude of units for different kinds of energy (e.g., fossil fuels are often reported in units such as 'oil equivalents,' whereas electricity is reported in kilowatt-hour). By contrast, an energy balance presents a consistent picture of inflows, conversion, and final use of energy within a defined socioeconomic system, usually a national economy. Energy balances are based on data from energy statistics but require also modeling related to incomplete or missing data for consistency reasons. Energy balances usually use only one unit.

The following notions are used to distinguish different stages of energy flows through an economy (Haas et al., 2008; Haberl, 2001a; IFIAS, 1974).

Primary energy is energy in the form in which it is extracted from the biosphere. This includes not only wood, coal, crude oil, natural gas, and heat derived from nuclear fission but also hydropower, wind power, solar energy, and heat from geothermal sources. In energy balances, primary energy use is generally approximated through the indicator 'total primary energy supply,' abbreviated TPES, which is the sum of the domestic extraction of primary energy plus the net import (=import minus export) of energy carriers. Therefore, TPES must not be equated with primary energy, in particular for countries for which the fraction of final energy carriers in energy import is substantial, but for many countries it is a reasonable, readily available proxy.

A multitude of conversion processes exist that convert primary energy into final energy carriers as used in households, service and commercial sectors, agriculture, manufacture, and industry. Prominent examples include the production of electricity in power plants, sometimes combined with cogeneration of heat for district heating and refineries that convert crude oil into a plethora of petroleum products.

Final energy is energy sold to final consumers. Final consumers are consumers that use the energy to generate useful energy and eventually energy services (see definitions below). Note that 'final energy' is an economic notion: Both households or companies may be final consumers; however, if energy is bought for conversion into another form of energy that is then sold, this is not considered part of the final energy use but of the conversion sector. Final energy carriers include fuel wood, wood chips, coal briquettes, coke, a variety of petroleum products such as gasoline, diesel, or heating oil, gas, electricity, or heat from a district heating plant. Energy balances usually report figures for final energy use, and the ratio of TPES to final energy use is to a certain extent informative with respect to an economy's energy efficiency.

Useful energy is the energy actually performing a certain task required to provide an energy service. Useful energy includes the mechanical energy needed to shape, move, or lift objects (stationary motors, vehicles); the heat required for heating or processing purposes; chemical energy needed in the chemical industry; light (radiant) energy; or the data processing services of computers. The transformation of final to useful energy is generally carried out by final consumers.

Energy services are the services for the sake of which energy is actually used (Lovins, 1979). Examples are manifold and include transport; establishment of suitable conditions within a building in terms of temperature, humidity, or illumination; cleaning of clothes; shaping of objects; chemical conversions; and many more. In contrast to primary, final, and useful energy, energy services cannot be measured in energy units – so

far, all attempts to define aggregate indicators for energy services have not produced satisfactory results.

There are several conventions that need to be considered when interpreting data from energy statistics and energy balances. In general, statistical offices usually report these together with the data or in separate methodological notes; failure to consult the respective documents in order to understand the definitions used may result in quite substantial misinterpretations. The two most important issues are noncombustible primary energy used in electricity generation and the distinction between gross and net calorific value. Different conventions are used to account for noncombustible energy (e.g., nuclear, wind, or water power, or geothermal energy) used in electricity generation; e.g., one may approximate the heat equivalent of the energy used or one may estimate that amount of fuel that would have been used in a thermal power plant producing the same amount of energy. Results from different methods may differ by large margins (factors of three or more). Gross calorific value (GCV) is the entire amount of energy released during combustion, including the energy released by condensation of water vapor in the flue gas; net calorific value (NCV) does not include this latter fraction. NCV is 5-15% smaller than GCV, depending on fuel.

The Energetic Part of Socioeconomic Metabolism

Preindustrial societies depended to a large extent on muscular power of humans or draught animals for their supply of mechanical energy. Additional primary energy inputs were wind and water power harnessed through mills as well as sailing boats (Smil, 1994). Despite their importance in terms of work supply for important activities such as grinding, forging, or transportation, these sources were quantitatively rather small. For example, in 1830, approximately 99% of Austria's primary energy supply consisted of biomass, most of which was used as food and feed (Krausmann and Haberl, 2002). Although the transition from agrarian to industrial society was driven by new energy sources, in particular fossil energy (Sieferle, 2001), biomass remained indispensable for socioeconomic metabolism as food and feed for humans and livestock. More inclusive concepts than those used in modern energy balances are hence required when analyzing preindustrial societies or long-term energy transitions (Fischer-Kowalski and Haberl, 2007).

Methods to account for the energetic aspects of socioeconomic metabolism in a manner that is conceptually consistent with material flow analysis (MFA) are primarily concerned with flows of biomass and muscular power. In principle, they follow the logic of energy balances as outlined in the previous section; i.e., they trace the flow of energy through the socioeconomic system from primary energy supply to useful energy (**Figure 1**). However, in doing so, these methods consider not only technical energy but also biomass and physical work (Haberl, 2001a,b). In contrast to conventional energy balances that account for biomass only if it is used in technical structures (e.g., in heating systems and power plants, or more recently as vehicle fuel), all 'metabolized' biomass is accounted for.

In short, these methods consider all energy crossing the nature–society boundary based on their physical energy content. Biomass is accounted for using the gross calorific value. Nutrition of humans and livestock is considered as an energy conversion process within society. Processing of primary biomass to food and feed is regarded as a conversion from primary to final energy. Food and feed are defined as final energy, and human as well as animal labor as useful energy (Haberl, 2001a). This allows construction of an energy flow analysis (EFA) framework that can be used to generate indicators such as

Figure 1 Flow chart of an energy flow analysis consistent with the material flow analysis approach as used in socioeconomic metabolism studies. Reprinted from Krausmann, F., Haberl, H., 2002. The process of industrialization from the perspective of energetic metabolism: Socioeconomic energy flows in Austria 1830–1995, Ecological Economics, 41 (2), pp. 177–201, Figure 1, with permission from Elsevier.

- Direct energy input: all energy entering a society (the same concept as 'direct material input' as used in MFA).
- Domestic energy consumption (DEC) is defined as direct energy input minus export (the same concept as 'domestic material consumption' as used in MFA).
- Indicators of final and useful energy as they are used in conventional energy balances.
- 'Hidden flows,' i.e., energy mobilized during energy extraction but not actually entering socioeconomic metabolism (e.g., crop residues).

EFA complements MFA methods to form the combined 'material and energy flow analysis' or the MEFA framework, which has been shown to be useful for studying sustainability (Haberl et al., 2004) and socioecological transitions (Haberl, 2001b; Krausmann and Haberl, 2002).

Embodied Energy and Emergy

The energy expended during production of a good and service, or in all products and services consumed in a national economy (or any other socioeconomic subsystem) is denoted as 'embodied energy' (Costanza, 1980). Embodied energy can be estimated using either input–output methods or life cycle assessment methods. Embodied energy is calculated using the system boundaries applied in conventional energy balances and EFA, whereas the concept of 'emergy' (Odum, 1996) traces all energy inputs back to one kind of available energy (exergy), usually solar energy. In this accounting framework, all biospheric energy conversions that are needed to produce any resource needed in a production process are traced back to the solar energy eventually required for them to happen and measured in 'solar equivalent joules,' abbreviated seJ.

Measures of Energy Efficiency and Quality

In physics, energy efficiency is defined as the relation between the input and output of energy in an energy conversion process. Energy efficiency (η) is defined as the ratio of energy output to energy input. η is dimensionless and may also be given as output in percent of input. This straightforward concept can, however, get a lot more complex when applied to socioeconomic systems due to the above-discussed questions of energy quality. Energy quality in this sense has largely two meanings (Cleveland et al., 1984; Hall et al., 1986): (1) the quality of energy in terms of its utility for performing certain tasks (which is often related to exergy) and (2) the quality of an energy source used by society (related to the efficiency with which it can be recovered from a source, i.e., its 'energy return on investment' or EROI).

Technoeconomic Concepts of Energy and Exergy Efficiency

An often-used measure of aggregate energy efficiency of a national economy is the ratio between the energy used and economic output, often measured as gross domestic product (GDP; *see* Data Bases and Statistical Systems: Economics (Statistical Systems); Environmental Economics). Relating these two variables results in an indicator of the form 'energy per GDP,' e.g., J US$$^{-1}$ or J €$^{-1}$. Of course, all issues related to the measurement of GDP need to be considered, e.g., whether it is measured in constant or nominal prices or how different currencies are converted (exchange rates or purchasing power parities).

Any of the above-discussed energy flow indicators (TPES, DEC, final energy, etc.) can be (and most likely has been) divided by GDP, but of course the meaning of the resulting efficiency measure, and accordingly its interpretation, will be different. For example, if measures of primary energy are used (DEC, TPES), improvements in the efficiency of conversion of primary to final energy show in the results, which is of course not the case if final energy data are analyzed. Such efficiency measures have been used in cross-country as well as longitudinal analyses, which almost always have shown quite substantial improvements in energy efficiency over time as well as along agrarian–industrial gradients (Fischer-Kowalski and Haberl, 2007).

However, as has been noted long ago (Cleveland et al., 1984; Hall et al., 1986), improvements of technoeconomic energy efficiency are only partially driven by improved technologies such as more efficient motors, heating systems, or power plants. While improvement of technical energy conversion efficiency has undoubtedly happened, long-term energy transitions (Grübler et al., 1999; Grübler, 2003) are also characterized by switches from thermodynamically poorer to superior kinds of energy, e.g., from biomass to coal to oil products to natural gas and electricity. Exergy is a useful concept for taking different qualities of energy sources into account (Ayres et al., 2003). This is particularly relevant when analyzing the role of energy for economic growth (Ayres and Warr, 2009).

Exergy is also relevant when considering technological measures to improve energy efficiency. For example, switching from oil to electricity for space heating may seem like an improvement of final energy efficiency because electrical resistance heating is 100% efficient, whereas the efficiency of heating systems based on fuel oil may be some 60–80%. In addition, electrical heating can be controlled a lot better than an oil-fired heating, saving additional amounts of final energy. However, switching from oil to electricity makes a lot less sense because converting the most valuable and versatile form of energy (electricity) into the lowest quality energy (low-temperature heat) is a huge waste of exergy. A much better way of using the exergy in the oil would be to switch to cogeneration of electricity and heat because any conversion of combustibles to electricity results in considerable energy losses in the form of waste heat due to the second law of thermodynamics. Waste heat can, however, be used for space heating if distributed through district heating grids, thereby raising the overall efficiency of the system in terms of both exergy and energy (Rosen et al., 2005).

Energy Return on Investment

One important consideration related to energy sources is how much energy society has to invest per unit of energy gained. The ratio of energy gained per unit of energy invested has been denoted as EROI. The calculation of EROI of different energy

sources is often denoted as 'net energy analysis' (Cleveland et al., 1984; Giampietro and Pimentel, 1991; Hall et al., 1986). Obviously, if EROI falls below one for a particular source of energy, then the process turns into an energy-losing activity instead of an activity delivering net energy to society. Industrial societies accept that in certain cases, e.g., in the case of many agricultural production activities that require more energy inputs than they deliver in terms of food calories (Krausmann, 2004; Pimentel et al., 1973). This is only possible because of the availability of other sources of net energy that can be used to energetically 'subsidize' food production.

Decarbonization

The notion of decarbonization relates to the reduction of carbon inputs to socioeconomic metabolism or of greenhouse gas (GHG) emissions such as CO_2 or CH_4. Indicators such as GHG emissions per unit of technical energy, e.g., per TPES, are widely used in climate-related discourses. They are often expressed as kilogram CO_2 equivalent per year. Different GHGs are converted into CO_2 equivalents according to their respective global warming potentials. Partial decarbonization can be achieved by increasing the share of low-GHG fuels such as hydropower in total energy supply. In theory, it is possible to reduce net carbon emissions to zero or even achieve net negative emissions if technologies such as bioenergy with carbon capture and sequestration are used on a large scale. However, on the input side, socioeconomic metabolism cannot be entirely decarbonized because biomass is indispensable for socioeconomic metabolism, at least as food and feed, and the carbon content of dry matter biomass amounts to 45–50% (Odum, 1971).

Conclusions

Methods of EFA are an important component of the toolkit of MEFA (Haberl et al., 2004) required for the empirical analysis of socioeconomic metabolism. While conventional energy balances and statistics provide a wealth of important information on the socioeconomic use of energy, for many instances they need to be complemented by additional data and methods to analyze important questions related to sustainability and society–nature interaction. EFA methods are available to trace socioeconomic energy flows in a manner that is consistent with MFA approaches. They are particularly important when analyzing preindustrial societies, but biomass and work flows not accounted for in conventional energy balances may be quantitatively important even for industrial economies. Measures of energy efficiency are required to optimize energy use and judge the quality of energy resources. Embodied energy is a useful concept to analyze indirect energy demand related to many products with no obvious relation to energy. Exergy is relevant for understanding differences in the quality of different kinds of energy that need to be taken into account when analyzing the role of energy for production processes and economic growth. Overall, EFA provides an indispensable framework and a variety of methods and tools for analyzing biophysical aspects of sustainability and society–nature interaction.

Abstract

The geography of energy analyzes societies' uses of energy and their relation to space. Rooted in historical transitions, the geography of energy follows some ordering principles such as the production chain and specific energy system dimensions. Using concepts of Euclidian space (distribution, distance, etc.), as well as specific spatialities, the geography of energy extends well beyond industrial geography, with social, political, agricultural, and environmental geography contributing to a deeper integrated view of the geographies of single fuels, energy technologies, energy regions, or even fundamental energy system transitions.

The Geography of Energy analyzes society's use of energy – as one of its fundamental resources – and its relation to spaces. This encompasses the natural systems as they provide energy in the form of fossil and renewable resources, the systems of energy production, conversion and provision to the users, the consumption of energy in all relevant sectors as well as the repercussions for and impacts on social and ecological systems. Starting from some fundamental ordering principles, mainly the production chain and the energy systems' dimensions, geographical conceptualizations of space and spatiality allow for specific approaches to analyze and explain the geographies of single fuels, energy technologies, energy regions and even fundamental energy system transitions.

Historical Energy Transitions

Energy is one of the primary building blocks of the functioning of all societies, be they prehistorical, historical, or contemporary, each era with their specific sociometabolic processes. The provision of functions like food production and processing, the manufacturing of raw materials and goods, and the operation of mobility, communication, and information technologies, among others, are based on the continuous and reliable supply of energy in its different forms. Regarding the geography of energy, all these options of supplying and using energy are organized in energy systems that have specific technical, economic, and political conditions and are directly linked with the environment and society. Thus, energy systems are inextricably embedded with physical space as well as with social spaces.

Historically, energy systems were based on the flow of energy provided by radiation intake from the sun, most of the energy forms we today summarize under the term of renewable energies. Thus, before the age of industrialization, most energy was derived mainly from wind, water, and biomass, and transformed by fire or animal or human muscle in an agrarian solar energy regime (Sieferle, 2001). This applies for mechanical energy and heat for processing, as well as for mobility through carts and ships. Further forms of renewable energies, such as geothermal, wave, or tidal energy, were only used under specific circumstances (**Table 1**).

With the industrial revolution, emerging mass production as well as mobility through railroads and steam ships were based on energy forms with a very high energy density. Traditional biomass as dominant primary energy source was replaced by fossil fuels like coal and – after the second half of the nineteenth century – also mineral oil. Similarly, steam and later electricity stepped in as higher quality secondary energy sources. They have accompanied fundamental social changes, including urbanization and mass consumerism, and also still fuel today's postmodern information and knowledge societies (Bridge et al., 2013).

Today, most global societies are in this fossil stage, with natural gas currently taking larger shares of the global fuel mix, notwithstanding some nations with considerable shares of nuclear power in their primary energy or the still relevant share of traditional biomass in many countries of low to medium development.

The reconsideration of renewable energies in recent times, based on technologies such as photovoltaic or concentrated solar power (CSP), or high-tech windmills, has not yet been able to replace the dominant share of fossil fuels of some two-thirds of global commercial energy demand; nor is it expected to be able to do so within the next few decades (IEA, 2012). The rise of emerging economies with their large populations and high dynamics of consumption patterns pushes global energy

Table 1 Overview of concepts of energy transitions (own compilation)

demand and leads these nations to rely largely on affordable and (domestically) available fuels and technologies, namely coal and oil; while the poorer parts of the Global South still struggle with sufficient supply and full coverage in replacing wood fuel and other forms of traditional biomass.

Organizational Principles and the Geography of Energy

Some fundamental characteristics of energy and the implemented energy systems place them squarely into geographical interest (Hamhaber, 2010).

- Being defined as a natural resource, energy straddles the connecting point between natural and social systems.
- Energy resources are distributed very unevenly, on all scales from global to local, as is the demand for it. These disjunct distributions of supply and demand pose the technological challenge to transport energy over ever increasing distances.
- Energy, energy production and conversion as well as energy consumption are highly relevant economically, as they fuel all activities and create respective markets on the supply and demand side.
- Energy use generates wide reaching environmental impacts on all scales from local emissions up to global climate change.
- This creates a societal challenge regarding access and affordability, be it local energy poverty or limited regional economic growth options due to unaffordable fuel supply. Obviously, the distribution of costs and benefits related to existing energy systems poses fundamental questions of social equity.
- Therefore, energy resources and their use are politically deeply contested – this reaches from local distributive conflicts of detrimental effects (such as 'not in my backyard,' NIMBY) up to hot conflicts to outright war ('blood for oil').

Given these characteristics of energy systems of obvious geographical interest, it seems surprising that the discipline has until recently not fully taken account of energy and energy systems as research topics. Despite the few available monographs (Manners, 1964; Sevette, 1976; Calzonetti and Solomon, 1985; Chapman, 1989; partly also Clark, 1990; lately Brücher, 2009) and quite some articles (e.g., ter Brugge, 1984), energy was never established as a subdiscipline or a research topic in its own right within (human) geography. Despite ample motivation for closer analysis provided by historical developments, such as oil crises, or single events like the nuclear accident in Chernobyl, geographers tended to scrutinize energy topics mainly from their subdisciplinary view.

Until recently, the geography of energy was typically considered a task of economic geography at large, and industrial geography in particular. Brücher (2009), however, considers several major differences of energy systems to other (production) industry sectors.

- Energy product variation is limited: Energetic resources mainly stay in the sector and will finally become energy products or energy services for the customer. Other industrial processes are not as inextricably linked to the given resource, or – vice versa – the resource can be converted into a multitude of products (e.g., steel into spoons, cars, construction material etc.). Thus, with the large exception of oil derivatives for chemical industries, energy production chains appear to be largely self-contained.
- The energy production chains are intensely vertically integrated: Despite their structure being similar to production chains in other industries, the energy industries, however, follow largely a narrow path with little deviations, called the imperative cohesion of the energy chain. Therefore, all energy markets show deeper links between the primary, secondary and tertiary sector than most other industries.
- Energy systems show market failures: the fordist character of most energy products creates massive economies of scale and, in centralized systems, typically requires large scale investments. Combined with technical conditions such as network-based distribution this has created mainly oligopolies and even monopolies. The transport and distribution grids of gas and power are considered natural monopolies, and even under the current deregulation regimes, the grid owner might be a single buyer (monopsist) or a monopolist service provider. To a lesser extent, also oil and coal industries show a tendency to oligopolistic structures.
- Energy is intensely regulated: an industry so important to society and with embedded market failures demands for close scrutiny and control by the state regulators. There is hardly any other industry under a similar political influence and interest in all countries. In many cases, the energy industries have been nationalized (electricity companies, oil companies, etc.) or remain in the ownership of smaller territorial political-administrative units. Often, cities have their own energy and service providers, as this often generates revenues, allows direct control of the sector and is a means for service provision by the states to their citizens.
- Energy harbors large conflict potential: as energy is not only a production factor for a single industry, but also a fundamental natural resource, conflict lines similar to those of water, land and minerals apply (see, e.g., the emerging debate on the energy-water food security nexus (Nexus, 2013)). More than for most other industries, many activities along the energy production chain are contested, be it mining, conversion in power plants or refineries, the large scale transport infrastructures, as well as the environmental repercussions.

Thus, the geography of energy may well be tackled from a perspective of industrial geography, among others, but has emerged as an interdisciplinary field that spans all three economic sectors with an extraordinary political influence, and deep social and environmental repercussions. Accordingly, other subdisciplines have found and lately renewed their interest in energy topics, among them urban geography, the geography of agriculture/forestry, political geography, and – to a lesser extent – social geography.

Regarding ordering principles, classical approaches toward a 'geography of energy' would apply an approach from industrial geography, along the production chain of energy systems. It reaches from primary energy (fossil fuels, solar radiation, uranium, etc.) through its conversion into secondary energy (electricity, diesel, etc.) to the end energy, and finally, provides

the energy service demanded (heat, light, mobility). On this production chain, specific activities are performed such as mining, processing, storing, transporting, enriching, distributing, and consuming. In each of these processes useful energy is lost; even the 'consumer' stage is nothing but a conversion and thus reduction of quality and energy contained in the fuel. This chain, however, is infused with other dimensions of the energy systems, and specifically, with spatial connotations.

Chapman (1989) stated that in order to mobilize and deliver energy, all societies created energy supply systems that respond to a specific spatiotemporal situation, the available technologies and other determinants. Such energy systems encompass six major dimensions.

- The functional dimension is defined largely by technological choices.
- The organizational one by the setup of major actors and stakeholders, their roles and the underlying regulation.
- The economic dimension focusses mainly on costs and benefits of such systems.
- The variables of the environmental dimension are the available resources and the residuals produced along the production chain.
- The social dimension encompasses values, perceptions, but also questions of equity.
- The social dimension encompasses values, perceptions, but also questions of equity.
- Finally, Chapman adds the spatial dimension regarding the location, distances and densities of and in such systems.

These dimensions are intrinsically linked: technology, for example, defines the energy resources and reserves of the globe, of nations, and of regions. Economic viability of resources is largely subdued to technological progress: drilling technologies to access deep-sea oil reserves have extended the peak-oil, fracking technology of shale gas collapsed the U.S. natural gas price and turned its role as net importer, or liquefying natural gas has allowed for marine transport compared to only transcontinental gas pipelines and thus created a new, global market. The dwindling price for photovoltaic solar modules is largely due to technological progress and economies of scale, and thus has created a globally marketable product which today even changes rural livelihoods in the least developed countries. Similarly, technological choices influence the nations' fuel mixes, as nuclear power, for example, delivers up to three quarters of electricity in France while other countries struggle for the right to access this technology as an energy source in politically contested arenas.

It may be argued that the political dimension is hidden in the organizational one, and Chapman insists on its large influence, but it seems largely underdefined, as the power of actors, their territorialities, or conflict potentials regarding energy systems are not covered by the organizational dimension. Brücher (2009) on the other hand even claims the political realm to be very gearbox linking all other dimensions of energy systems (see **Figure 1**), mediating between the energy systems proper (production chain), and their external socio-economic and spatial conditions.

Figure 1 Energy systems model: the production chain in its interrelation to socio-economic and spatial conditions (after Brücher, W., 2009. Energiegeographie – Wechselwirkungen zwischen Ressourcen, Raum und Politik. – Studienbücher der Geographie. Borntraeger, p. 280, modified).

Here, however, the question remains how the energy systems – including all their dimensions – are spatial phenomena. In Figure 1, such spatial relations are twofold: the spatial allocation of the energy systems' production chain is specific for each energy source from primary to secondary to end energy, and externally, explicitly spatial conditions are named as being influenced and influencing the energy system such as other infrastructures like transport, climate and climate change, or settlement patterns. Beyond the debate, whether industrial structures may not also be seen as spatial conditions to the energy system, this opens the discourse on how to relate energy systems with different connotations of space, before these aspects are integrated into some specific approaches of a geography of energy.

Energy Systems and Euclidian Space

The geography of energy in a classical sense typically is understood as all spatial expressions of the energy systems in space, as well as the adaptation of such systems to spatial conditions. Therefore, instead of describing the ever changing spatial status of energy systems here by fuels, rather the different gradations of Euclidian space are explored in their explanatory value to energy systems.

Spatial Distribution: As shortly sketched above, the distribution patterns of both energy resources and demand are massively uneven. With some 70% of all conventional oil and gas reserves allocated in the so-called strategic ellipse, encompassing the Gulf region and stretching north into Central Asia and Western Siberia, the basic layout of the global oil and gas markets was determined for decades. With the rise of new exploration and exploitation technologies (deep-sea drilling, fracking, etc.) energetic resources such as arctic, deep-sea and nonconventional oil and gas have turned into economically viable reserves, shifting the playing field and possibly turning the tables for oil-exporters and importers ('golden age of gas,' IEA, 2012). Also, new players have entered the game, mainly with large new resources in Latin American and Sub-Saharan African countries.

Similarly, the potentials for renewable energies are distributed according to the natural endowments of geology, climate, and ecology. As the hydroenergy potentials of higher latitudes are largely exploited, the focus moves to the inner tropics and the foot range of the Tibetian plateau. The solar potential, however, is highest in the dry belts along the tropics, especially for CSP, similarly, wind, tidal, deep geothermal, and also bioenergies have their specific geographies (Geni, 2013).

On the other hand, the demand distribution is also massively lopsided, with the countries of the classical economic triad being the largest consumers, in total numbers as well as in per capita demand. Nowadays, a more multipolar world finds its expression also in a wider distribution of energy demand, with the emerging economies, above all China, emerging as major consumers and therefore shifting the flows of energy on a global scale (IEA, 2012). As obviously 'resources are not, they become,' the global fossil fuel map is constantly been redrawn.

Spatial allocation: The allocation of activities along the energy production chain is determined by the characteristics of different fuels. Accordingly, industries have emerged that produce and provide fossil fuels on a global scale. The oligopoly of the oil-producing seven sisters has been replaced and counteracted by the production oligopoly of the oil-exporting countries. During this shift also the allocation of the related physical infrastructure such as pipelines, refineries, and terminals has been relocated from the consumer's countries to the producers. Similarly, the transportation infrastructure starts to specialize toward pipelines and tankers for refined products. Hence, large parts of the value chain have been reallocated to the oil-producing countries which before had been mere exporters of raw products (Clark, 1990).

Scale: Accordingly, depending on the fuel source, energy markets of different sizes have evolved. Based on the energy density, the transportability and related costs, and the ease of use and conversion of the fuels, their markets are either global (as oil) to continental (for pipeline based natural gas networks) or national as is typical for electricity networks and markets down to simply local networks for wood fuel and wood chips. As this is a function of physical distance it fits very well into the concepts of Euclidean space and traditional economic geography.

This leads to new concepts of rescaling, as illustrated in integrated continental to trans-continental energy systems. The 'Desertec' scheme, for example, envisioned to provide electricity from CSP mega-projects in the Sahara not only to Northern Africa, but to Europe as well. Combined on continental scale with hydropower from Scandinavia and the Alps, wind from the maritime climate regions along the Atlantic coast and bioenergies produced in Eastern Europe, this concept aims at capitalizing on the qualities of each energy source to compensate for the respective weaknesses through a high-voltage transcontinental and circum-Mediterranean transmission grid, thus creating a new, continental geography of electrical energy in Europe. Similarly, on smaller scale, the deep transition to renewables in Germany ('Energiewende') demands for new grid capacity to absorb the shifts toward a new geography of power production, as the distribution of production capacity shifts with predominant wind and bioenergy resources in the North while some nuclear power plants in the South are being decommissioned.

Centrality: A special, spatial characteristic of energy systems is their level of centrality. As discussed above, most energy systems have emerged as being large-scale monopolistic or oligopolistic structures. Especially the network-based electricity system, where the fuel is not storable economically in large amounts, requires an immediate adaptation of the supply to the demand curve. Based on the high investment, potentially sunk costs, and the regional integration of the system grid, the electricity industry historically has been organized as fully vertically integrated systems. With the move toward nuclear power production, a technology that has large security considerations, a fundamental debate about central versus decentral energy systems emerged. Amory Lovins, a protagonist of that debate in the United States even stated a pending decision between decentral, community-based, low to medium technology, environmentally safe systems that fostered democratic participation and a sense of ownership on the one hand, and centralized, high tech, expert based, high risk technologies that would demand also a high-security state, alienate the

citizens and thus threaten democratic structures. As these two system typologies were perceived as being mutually exclusive, such a decision was assumed as irreversible (Lovins, 1977). Today, during the fundamental transition from fossil to renewable energy systems, both, central and decentral system elements are embedded in the current markets, such as in Germany with a large share of consumer owned small-scale solar photovoltaics side-by-side with base load nuclear and lignite power plants. Nevertheless, the centrality of energy systems remains a fundamental category of geographical description and analysis.

Based on the concept of centrality and spatial distribution patterns, Brücher (2009) conceived major phases of paradigmatic spatial characteristics of energy systems, regarding their dispersion and concentration in space. Where, before the industrial age, energy was derived from largely dispersed natural sources ('energy from space'), the highly concentrated fossil fuels and the emergent technologies growing with economies of scale created specific highly centralized production and distribution systems ('energy for space'). With the return to renewable energy sources in their low energy density (e.g., solar radiation), the principles of a distributed production and potentially decentralized supply systems (and thus 'energy from space') regain importance, including the conflict potentials due to competing uses of that same space (food, fodder, fiber, fuel).

New Spatialities of Energy Systems

The Geography of Energy as based on Euclidian space can clearly describe the distribution of resources and the allocation of functions of the energy production chains as original geographical contributions to the debate. Using sheer physical distance as determinant of the emergent systems, however, is unsatisfactory at least. Certainly, transport technology and related costs play a major role in decision making. Beyond the (economics of) physical space, further dimensions of the energy systems have to be considered. Energy systems are always steered largely by their organizational structure and thus the stakeholders' interests. Also, their repercussions in the social and environmental realms have gained importance in discourse and decision making, rendering energy a sector that is highly politically contested.

According to this understanding, the Geography of Energy also considers the social construction of space(s) as analytical framework for energy systems. This is in line with a paradigmatic theoretical turn of the wider discipline, where socially constructed spaces have complemented, if not largely replaced Euclidian space as reference for analysis in human geography. Thus, the approach goes well beyond the description on distributions or centrality: if e.g., politics is assumed as a 'gearbox' for all societal decisions regarding energy systems, a political–geographical approach has to include social science approaches to space. Similarly, economic geography, where the Geography of Energy traditionally would have been subsumed, has moved widely beyond classical allocational quests and has largely left Euclidian space behind. Thus, it should be ensured that the application of physical space should not extend beyond the physical world, whereas the mental and social spheres demand for their specific spatial reference systems (e.g., spatiality according to Soja, 1989; Harvey, 1996, and others). To comprehensively analyze energy systems, therefore, they have to be localized also in socially constructed space(s). From this standpoint, energy has clearly emerged with new urgency as a research subject in many subdisciplines of geography, and has been infused with spatial connotations beyond physical space. The approaches of a reformed (e.g., relational) economic geography (see, e.g., Bathelt and Glückler, 2011) help explain the shift of energy systems from a modern, mass producing energy supply infrastructure based on economies of scale to a postmodern, customer oriented service industry where power is 'green' and customers are willing to pay a primer on electrons delivered from windmills and solar systems. With the theoretical turn enter further conceptual geographical approaches to analyze energy systems with higher explanatory value. A selection will be explored in the following paragraphs.

Relative location: Other than absolute location, relative location is based on the concepts of relations of elements in a system, and thus shows the production chain not only as an interlinked, sequential set of physical locations, but rather as interdependent positions subdued to economic and time distances. A change in transport technology creates new conversion locations at the sea, be it refineries in Rotterdam, energy dependent industries such as aluminum smelters in Iceland and Quebec, or, quite recently, new terminals for liquified natural gas (LNG) tankers. New relative positions will therefore create an effect in physical space, shifting, and reallocating the product chain's elements of the world's map. Similarly, the upstream–downstream position in a network has deep repercussions on the reliability of supply, as has been proven by the Russian–Ukrainian gas dispute, effectively shutting down the supply to Europe as customer 'behind' the transit country (similarly for the UK position, see Bridge et al., 2013).

Centrality, Contiguity, and Connectivity: the concept of centrality may not fully grasp this interdependency of elements in a system. Going beyond, contiguity may grasp dispersion, whereas connectivity measures the intensity of interlinkages in a system. In a typology provided by Bridge et al. (2013), these characteristics are juxtaposed for different forms of energy systems, and by that display the fundamentally different character of systemic choices of potential energy futures, societies have to take. This also illustrates very well Lovins' (1976) argument of incompatibility of central and decentral systems. It also unveils how the debates that emerge about central or decentral systems during deep transitions to low-carbon societies hide deeper, relational characteristics, and mask distributive conflicts among actors in the field (**Table 2**).

Evolutive approaches and path dependency: structures of energy systems tend to display a high inertia to change. Many of the decision and actions in such systems may be contingent in specific structure-agency dynamics, often reconstructing existing structures whereas new, emergent structures would have to be implemented against the prevailing dominant form (Bathelt and Glückler, 2011). As an example, only due to the systematic crisis of the power industries in the 1980s and 1990s the formerly accepted vertical integration of the electricity production chain was put under scrutiny. At the same time, information and communication technology provided for

Table 2 Spatialities of energy infrastructure networks

Illustrative spatial form	*Contiguity*	*Connectivity*	*Centralization of capacity and supply decisions*
District heating system	High	High	Locally high Nationally low
National electricity grid (monopolistic)	Low	High	High
Continental gas pipeline	Low	Low	High
National electricity grid (with independent suppliers)	Low	High	Low
Off-grid 'island'/decentral electricity generation	High	Low	Internally high Externally low

After Bridge, G., Bouzarovski, S., Bradshaw, M.J., Eyre, N., 2013. Geographies of energy transition: space, place and the low-carbon economy. Energy Policy 53, 331–340.

a more complex coordination of supply and demand. This allowed for a vertical disintegration of the production chain, created new stakeholders (such as Independent Power Producers and Bulk Electricity Traders) and paved the way for the creation of a new market of electricity trade with platforms and new products such as futures and options. This unbundling has in many countries changed also the market mechanisms for price building and investment allocations. This immense repercussion on the economics of the power system shifted the whole market organization, and thus the roles and relations of all actors, who in turn again influence the design of future energy policies.

In this line of thought, also technological development remains a major driver for the emergent geographies of energy also under relational perspectives. It has for example deeply influenced the environmental debate, where for a long time negative externalities have been relocated spatially, temporally and between social groups. With a shift to integrate such externalities, end-of-pipe-technologies of fossil-fuel based power production are being (partly) replaced by integrated system approaches of green houses gases (GHG) emission mitigation, including the efficiency of (individual) mobility, homes, and household appliances (UNFCCC, 2013).

Also, economic geography has scrutinized the technology markets from a relational approach, as these technologies, e.g., solar energy, have created industrial clusters and regions of research and production and, recently, with a reduced pace of innovation, a massive shift of production to low-wage countries. As for another example, technological progress may be subdued to a strong path-dependency: in centralized and mass-production oriented systems, technological change demands a coevolution of production and demand side. This is clearly visible in the automotive industry where a shift toward electrical cars or – even more revolutionary – to hydrogen is retarded by a technological lock-in of the coupling of the existing car fleet with the dominant (fossil fuel) supply networks.

Spatial images and narratives: As we have seen, energy policy moderates between – and sometimes dominates – the energy production chain on the one hand, and the larger societal framework and environments of the energy system on the other. This includes an understanding of what may be called a 'double impact of space,' as societal decisions form the spatial structure of energy systems consciously or unwillingly, and – reciprocally – the spatial structure of the systems (pre-) determines the options for further societal choices. This figure of thought, however, remains rooted in approaches of physical space, as it tends to assign an active power or action to physical space and its conditions. Therefore, geography's understanding of energy systems has moved beyond and complemented this by approaches such as the construction of spatial images. The allocation of large infrastructures for example is based on the narratives of the different actors regarding the affected space: in the case of hydropower megaprojects in Northern Canada, it is depicted as 'nordic desert' and thus practically 'empty' space from promoters of the project, whereas the opponents refer to 'mother nature' as an imagination of the values of indigenous people and of nature itself (Hamhaber, 2004).

Social networks and interaction: Even more consequently, constructivist approaches not only explain the respective actors' images and definitions of, in short, their perspectives on energy systems in the process of societal negotiation. They also allow it to map the actors themselves within their respective social spaces, including their socially defined barriers, their options and their freedom to decide and to act. Active strategies of territoriality, regionalization, and scaling have been applied to explain energy-system driven conflicts as processes of transgression, as exclusion and inclusion strategies and efforts to gain and prohibit access to energy and to the participation in strategic societal decisions on future energy systems (Hamhaber, 2004). Obviously, there are many more options for a political science approach toward negotiations and conflict about energy systems, be it on renewable energy infrastructure such as wind parks, grid expansion, or, more traditionally, on oil production and pipelines. Certainly, not in all cases, social science approaches of large theoretical reach have to be applied, there is, however, a demand for theoretically informed approaches to analyze and explain energy systems and their dynamics.

Geographies of Energy Systems and Their Transition

The dimensions of energy systems allow for selective and focused research, often from the perspective of specific geographical subdisciplines. Going beyond, more integrated perspectives describe and explain the complexity of energy systems, their spatialities and their transitions.

Geographical Energy System Analyses

Geographical analyses of (commercial) energy system represent the current status of the resources potentials of a given region, the supply structures along the production chain through the primary, secondary, and tertiary sector, and the specific demands for energy services, with their technological, economic, social, and environmental dimensions, in order to allow for an integrated view of a regionally defined energy system. Here, energy geography investigates the global energy flows and their specific repercussions with social and environmental spheres, including a global energy and climate governance. On continental levels, the continuing integration of

markets (such as the network based natural gas and electricity markets in Europe or the regional efforts for grid connections in South-East Asia or in Eastern Africa) are understood as scalar shift and thus one form of energy system transitions (see below). However, most trans-boundary cooperation to day still is in the making and rather limited with the notable exception of the supranational energy policy of the European Union.

Thus, the national level still remains as the most relevant scale for energy system analyses as most policy and economic decisions refer to that spatial reference, at best avoiding the risk of falling back into an understanding of nations as territorial 'container.' Such analyses incorporate demand sectors, namely traffic, industrial processes, and buildings with their energy service demands for mobility, high and low temperature heat, light, and information and communication technologies (ICT), in their historical and current structure as well as with forecasts and scenarios, based on demographic, economic, and further indicators. Regarding national scale energy systems, the territorial frame dominates the debates: therefore, concepts of autarky and import/export energy flows gain massive relevance to policies, economics and also social issues. Thus, some countries such as Mexico or Ecuador are net exporters of crude oil, but import oil derivates. This may put a massive burden on national budgets especially when combined with energy subsidies. Obviously, social and political implications are included in such energy system analyses. Also, spatial repercussions of forecasted trends or policies are in the focus of the geography of energy. These include land use shifts related to altering primary fuel mixes.

Energy Landscapes and Energy Regions

Other than the territorial approach to energy systems, another line of argument follows the line of 'energy landscapes' as an integrated view of a region predominantly determined by energy resources exploitation, transformation and/or use (e.g., the Ruhr valley in Germany, sometimes also referred to as an 'energy region').

Here, fossil fuel landscapes may be distinguished from landscapes of renewable energies (Zimmerer, 2011), as they impose themselves on space in fundamentally different ways, and – finally – find expression in physical structures. As the success of fossil fuels is based on their high energy density, their local impact in different steps along the production chain can be massive, with open-pit exploitation literally eating away landscapes and geo-engineering creating new, post-mining ones. Also, urbanization during industrialization was largely determined in its location and development by the availability of (fossil) energy resources (see agglomerations based on coal mining in central Europe and England, Sieferle, 2001). Similarly, the current structural change after deindustrialization partly was triggered by those resources becoming exhausted or noncompetitive. In that context, some regions today reinvent themselves as postindustrial energy regions in reinterpreting their industrial heritage as cultural part of a new regional definition.

In comparison, renewable energies are largely dispersed in space and thus contribute to landscape transformation by new infrastructural installations. Transitions in agriculture and forestry triggered by energy transitions are partly massive. These are widely debated in geography of energy in regards to their impact on existing (cultural) landscapes, these impacts being one of the major reasons for conflicts about widespread installations of e.g., wind power or pumped storage systems or the impact of large-scale biofuel production in tropical rainforests. Finally, there may also be emergent 'landscapes of energy consumption' (for detailed examples see Zimmerer, 2011).

As this label, however, includes assessments of energy poverty or regulation regimes, the term 'landscape' is partly used in a traditional, integrated way as the 'character' of a given region (an energy landscape in the sense that it was or is determined predominantly by energy systems), and partly in a metaphorical sense ('Electricity Landscape' for the sociopolitical regime of the power sector of a country). Thus, the term 'energy landscape' often seems more like a simplistic ordering principle or rather an oscillating label than a scientifically sustained and fully elaborated spatial terminology (a comprehensive debate of the term landscape/'Landschaft' and its explanatory value was at the core especially of German geography).

The Geography of Energy (System) Transitions

Adding a distinctive temporal perspective leads to the analysis of transitions of energy systems, tackling the current paradigmatic shift of whole nations, of regions and also small-scale communities from fossil to postfossil energy systems. Bridge et al. (2013) define such energy transitions as "fundamentally a geographical process that involves reconfiguring current spatial patterns of economic and social activity." It has to be mentioned, however, that "there is no consensus on a desired end state" of such transition (Bridge et al., 2013), as the concurrent transition from traditional fuels to modern energy systems as depicted in rural electrification in developing countries is a similarly deep transformation and – according to the introducing arguments – also a paradigmatic change.

Such transitions are part and parcel of a profound restructuring of the societies affected. Post-oil societies that were deeply dependent on oil exports, mainly in the Gulf region, currently reinvent and redesign their national economies toward service and financial industries, tourism and airlines. Other former export nations and soon-to-be importers like Indonesia and Mexico have already diversified their economies and thus may be seen as half-way between postoil and postfossil societies. At the same time, some nations such as Angola, Ghana, and Ruanda currently experience the impacts of becoming oil producing countries with all related economic benefits and social and environmental challenges, including the deep disruptions of their social fabric labeled as the curse of the resource.

Industrialized nations on the other hand are challenged by the quest for postfossil societies, the total transformation of their energy systems in a shift from fossil-fuel import dependency to renewables and highly efficient energy systems. This becomes even more demanding when combined with a decision for a fast nuclear exit. Such transitions always come with disruptions, conflict potentials and negotiations on objectives, measures and consequences, in short, the distribution of costs and benefits that are specific for the system under transition. Thus, in Germany, as one of the wealthiest countries on the

globe and despite a large majority supporting the transition, debates still proliferate about misallocations of subsidies for biofuels and photovoltaics (PV), the costs and affordability of electricity for poor people, the equity of benefits distribution between companies, homeowners and tenants, or the obligations of market participants to cover costs of the transition. Given this complexity, is appears disconcerting that the International Energy Agency (IEA, 2012) claims the need for all nations to follow such a model of deep energy transition in order to mitigate greenhouse gases to reach the 2 °C target to prevent deep climate change.

Conclusion

The Geography of Energy in most reports of the international institutions involved in energy and/or climate change still is built upon a traditional Euclidian conceptualization of space. More often than not, reporting remains based on national statistics, understanding the energy system from a locational and traditional territorial viewpoint, and depicting energy facts in tables and maps supporting this view (IEA, 2012). Here, geographical analysis can contribute to a comprehensive understanding of energy systems, as it allows for a customary description of energy systems following accepted conventions, where the production chain, the scales and the relevant dimensions of energy systems remain valid as ordering principles.

Building upon this, and going beyond, examining the new spatialities of energy systems carries more explanatory value, as they do not put (physical) space in the center of analysis, but rather the interrelations, contextualities, interests, etc. In short, such analysis may unveil deeper drivers for the multiple spatial structures and processes that constituted the old and push forward the new emergent geographies (pl.) of energy and provide an integrated, systemic view of how societies negotiate, define and create their energy systems. The discipline may help to overcome bounded perspectives, and thus also normatively contribute to the transitions toward more sustainable geographies of energy.

Abstract

This article highlights the growing need to understand the situated commitments and practices of engineers and engineering. It asks: What is engineering for? What are engineers for? Much research challenges images of normative holism and technical–social dualism. The first equates engineering practices with material advancements for humanity as a whole. The second demarcates technical contents of engineering work from social practices that engineers participate in as people. Critical analyses examine images of engineers serving a profession, private industry, and the nation, state, or country, as well as producing technology through design and protecting gender, racial, heterosexual, and developmental privilege. Each delineates pathways for critical participation.

We live in highly engineered worlds. Engineers play crucial roles in the normative direction of localized knowledge and social orders. This article highlights the growing need to understand the situated commitments and practices of engineers and engineering. It asks: What is engineering for? What are engineers for?

Drawing from a diverse arena of research, teaching, and outreach, this article raises awareness of how engineers imagine themselves in service to humanity, and how their service ideals impact the defining and solving of problems with multiple ends and variable consequences. It does so by examining relationships among technical and nontechnical dimensions, and how these relationships change over time and from place to place. Its researchers often are critical participants in the practices of education and work that they study.

Engineering studies scholars conduct historical, social, cultural, political, philosophical, rhetorical, and organizational research on engineers and engineering, paying particular attention to normative directionality in engineering epistemologies, practices, identities, and outcomes. Areas of concern include engineering formation, engineering work, engineering design, equity in engineering (gender, racial, ethnic, class, geopolitical), and engineering service to society.

This article thus pursues three related missions: (1) advance critical analysis and understanding of engineers, engineering, and outcomes of engineering work; (2) help build and serve communities of researchers and learners in engineering studies; and (3) expand critical participation in engineering education, research, practice, policy, and representation as important practices of knowledge production and scalable scholarship.

Building Engineering Studies

During the 2002 joint meeting of the Society for Social Studies of Science (4S) and the Society for History of Technology (SHOT), a gathering of 19 attendees expressed interest in establishing a scholarly network devoted to engineering studies. In the 1989 review essay, "The Invisible Engineer: How Engineering Ceased to Be a Problem in Science and Technology Studies," Gary Downey et al. (1989) documented how researchers in sociology, philosophy, and history had treated engineering and engineers as intellectually uninteresting, albeit for different reasons. Things had changed by 1994. In the more optimistic essay, 'Engineering Studies,' Downey and Juan Lucena traced expanding work by social scientists and humanists on questions of engineering knowledge, technical work, gender in engineering, and scholarly reflections by engineers on engineering (Downey and Lucena, 1994).

Despite the significant amount of available research, engineers and engineering still had limited visibility in the science and technology studies (STS) literature in 2002, except for playing cameo roles, serving some other purpose. One way the word 'engineering' frequently appears to this day is as a metaphor for the contingent work of construction. John Law's (1987) concept of heterogeneous engineering is not about engineers and engineering but the construction of technology. Another way is as a substitute or equivalent term for technology. Gabrielle Hecht, a prominent technology studies scholar, argued in 2005 (Valderrama et al., 2005: p. 13) against establishing a field of engineering studies because it demanded understanding how engineering might be different epistemologically from other forms of technological knowledge. This is a fair question. What if the answer is that engineering is more than a form of technological knowledge?

By 2002, many researchers were finding engineering and engineers to offer a significant collection of research sites for investigating forms of knowledge and material practices with normative commitments and directionality. The issue of normativity is central to studies of engineers and engineering. In 2008, the engineering studies scholar Ronald Kline (2008) argued that Edwin Layton's (1986[1971]) *The Revolt of the Engineers* became a classic that is still widely read because it reported and accounted for struggles between progressive and conservative engineers in the early twentieth century. In the formative work *Engineering the Revolution*, Ken Alder (1997: p. 60) found engineers across eighteenth-century France seeking "to describe quantitatively the relationship among measurable quantities, and then to use these descriptions to seek a region of optimal gain." What sorts of commitments live in optimal gain through engineering?

Despite growing momentum, many scholars in STS and history of technology found it difficult to advance research projects on engineers and engineering because academic

departments, publication outlets, grant agencies, and even professional societies continued to place primary emphasis on the terms 'science' and 'technology.' The work of building a networked arena of research in engineering studies started with the premise that engineers and engineering can and should be analyzed as central rather than peripheral actors and practices in worlds of science and technology. The International Network for Engineering Studies (INES) was established in Paris in 2004 at the joint meeting of 4S and the European Association for Studies of Science and Technology. Imagining a network whose participants had primary allegiances to many different organizations, INES would help advance research, teaching, and outreach in engineering studies.

Beginning in 2006, INES held workshops in Blacksburg, Virginia; Lisbon, Portugal; Grafton, New York; Cleveland, Ohio; and Copenhagen, Denmark. Also in 2006, INES members began organizing INES-affiliated paper sessions at 4S and SHOT meetings. The INES Web site hosts a large bibliography of research in engineering studies. In 2009, Taylor & Francis/Routledge began publishing *Engineering Studies: Journal of the International Network for Engineering Studies*. Morgan & Claypool began publishing the engineering studies series *Global Engineering* in 2011. In 2012, the MIT Press began publishing the capstone book series *Engineering Studies*.

INES emerged in the company of seven related initiatives in the humanistic and social science study of engineers and engineering:

1. In 2000, members of the Liberal Education Division of the American Society of Engineering Education began to respond to new accreditation criteria for engineering programs with research and learning practices that would go beyond bringing engineering students to liberal education and highlight the critical participation of liberal education practices within engineering education. Acknowledging a significant expansion of participation by members interested in critical participation within engineering education, members of that division changed its name in 2011 to the Liberal Education/Engineering & Society Division.
2. In 2002, in Europe, an international collection of historians began to organize meetings and publications for rethinking the history and current status of engineering formation and practice.
3. In 2004, scholar-activists interested in engineering and social justice began to establish a series of paper sessions, workshops, and conferences; the Morgan & Claypool book series *Engineers, Society, and Technology* in 2006; the *Engineering, Social Justice, and Peace* network in 2010; and the *International Journal of Engineering, Social Justice, and Peace* in 2011.
4. In 2005, historians of engineering in SHOT who were interested in reestablishing linkages to engineering education and training established the special interest group Prometheans.
5. In 2006, in a series of workshops and book collections, philosophers affiliated with the Society for Philosophy of Technology began mapping out a philosophy of engineering and its relations to the philosophy of technology. In 2009, Springer began publishing a series on Philosophy of Engineering and Technology.
6. In 2009, after several years of producing a semiannual publication dedicated to engineering studies, Chinese philosophers and social scientists launched the *Journal of Engineering Studies*. Across the country in which the main word for engineering means 'large technological projects,' the domain covered by engineering studies includes not only trained engineers, but everyone else involved in and affected by large technological projects.
7. Finally, an unprecedented scale of reform activities in engineering education across the planet during the 1990s and early 2000s stimulated the emergence of a scholarly field of engineering education research from within faculties of engineering. The field is built on normative commitments to change engineering education, on the premise that educators will be persuaded to alter pedagogy and curricula only when presented with rigorous research demonstrating better learning outcomes through alternative practices. Researchers in the American Society for Engineering Education, European Society for Engineering Education, and Australasian Association for Engineering Education have taken the lead, especially through the *Journal of Engineering Education*, *European Journal of Engineering Education*, and *Australasian Journal of Engineering Education*.

While many participants in these latter initiatives also contributed to the formal development of INES and engineering studies, many also did not identify their scholarship in the first instance with the label 'engineering studies.'

What Is Engineering for? What Are Engineers for?

Making visible the pursuits of optimal gain and the commitments that live in them requires one to confront the question: What is engineering for? Since one can find normative commitments in the personal orientations and service ideals of engineers, inquiring into what engineering is for necessarily involves examining the identities of engineers. It means that work in engineering studies pays much greater attention than other fields of STS to the formation – the education and training – of practitioners. It also requires asking: What are engineers for? (Downey, 2009).

Researchers in engineering studies regularly confront a dominant image of engineering work as a contribution to human advancement as a whole. Leaders who promote engineering throughout the world have long emphasized how the profession contributes directly to human progress. Although they look through different lenses and pursue variable objectives and material visions, they have tended to assert an equivalence between the technical contents of engineering practice and material benefits they achieve for a common humanity. The most prominent feature of these normative projects is their holism: as though the making of engineers produces people who contribute to human advancement as a whole (Downey, 2012).

The normative commitment to holism in engineering has far-reaching implications. It grounds what Wendy Faulkner (2007) has called technical–social dualism. Technical–social dualism is the sharp division engineers draw between the technical contents of their work and the social practices in

which they participate as people. Engineers routinely portray the core of engineering work as wholly technical in content, built on the engineering sciences, and culminating in technological designs. Both as individuals and as a collectivity, engineers learn to encounter and engage with flows of experience as endless sources of technical problems to solve, seeking optimal gain through technological design on behalf of humanity as a whole.

One implication of technical–social dualism is that distinctions among different fields and disciplines of engineering become functional technical differences that complement one another. This applies, for example, to the fields of civil, mechanical, electrical, and chemical engineering, as well as to the disciplines of mechanics, circuit theory, thermodynamics, and vibration analysis. While material practices performed on the job may range from design to manufacturing to sales, technical learning in the engineering sciences provides the core preparation for all of them.

The output of the engineering sciences that feeds into technological design is especially significant. Until fairly recently, engineers have been relatively free to claim jurisdiction over the design and development of new technologies, without competition from other knowledge workers. The absence of competition made it easy for both engineers and nonengineers to equate engineering with technology, frequently to the point of confusion. Engineers design technologies, and the making of engineers is always about the making of technologists. The image authorizes narrowness in the making of engineers and performance of engineering. Since quality engineering work produces technological outcomes that benefit humanity, engineers must be careful only to make sure that nothing interferes with the high-quality technical practices they learned in school and in subsequent training.

Much work in engineering studies begins, both explicitly and implicitly, with critical reactions to normative holism in engineering formation and practice. Most work, in fact, calls attention to the limitations of normative holism by demonstrating how it is inconsistent with actual features of engineering formation and practice. Practitioners of engineering studies then try to make visible the complex sociotechnical relationships that normative holism hides.

Engineers typically make technical–social dualism a basic assumption, an ontological given, for understanding, characterizing, and performing their work. Taking a practice as given grants it normative authority. As a result, research that examines relationships between the so-called technical and the nontechnical dimensions of engineering practice necessarily takes on normative contents of its own. It gains directionality, or assigned value, in relation to the image and practices of normative holism.

Even simple descriptions of relationships between technical and nontechnical agencies in the making of engineers raise the possibility that practices of engineering teaching, learning, and work might have been otherwise, could become otherwise, and, hence, possibly should be otherwise. Indeed, when one diligently pursues the fundamental questions – What is engineering for, and what are engineers for? – a resolute and narrowly defined commitment to normative holism can appear at best delusional, and at worst conspiratorial. It hides other normativities.

Critiques of engineering and engineers thus entail an openness to potential practices of critical participation. The scholarly work of conceptualizing and enacting critical participation is at least as difficult, if not more so, than critical analysis alone. It is knowledge production that requires accepting engineers, makers of engineers, future engineers, and advocates of engineering as audiences, along with fellow scholars in engineering studies. It involves calibrating theoretical and methodological agendas to include the possibility of nominating and scaling up, or achieving the status of givens, of alternative images and material practices.

Critical participation cannot happen without critique. Yet limiting research to critique risks limiting engineering studies to armchair analysis, with the hope that fellow scholars will embrace its virtuosity and then facilitate its diffusion to outside publics. It thus risks limiting itself to what the social critic Ivan Illich sarcastically characterized in 1968 as 'good intentions.' His argument was "To hell with good intentions" (Illich, 1968 [1990]).

A common scholarly competition in engineering studies is over how to formulate and scale up alternative images and practices by pairing critique with critical participation in such a way that makes visible what technical–social dualism hides and which assesses the implications of granting it more prominence. Neither the knowledge contents nor the normative contents of such work can be specified in advance. The competition is friendly. As long as normative holism and technical–social dualism remain invisible as givens in the making of engineers and engineering work, engineers will have no reason to reflect critically on either their commitments or the sociotechnical outcomes of their work.

The balance of this article briefly introduces a range of critiques of normative holism and technical social–dualism. It also highlights the possibilities generated by likely pathways for critical participation, and the difficulties posed by likely challenges.

For a Profession?

A persistent and vexed issue, especially in the United States and the United Kingdom, has been the tendency of engineers to claim the status of an autonomous profession. The claim itself is understandable. Embracing human progress as a whole grants the work of engineers a special kind of autonomy that seems analogous to holistic service in the classical professions of law, medicine, and divinity. Professionals serve the community as a whole. The difficulty with working engineers has been that they largely do not fit the image. This raises difficult questions for the project of building engineering formation around normative holism.

During the 1960s and 1970s, American sociologists struggled unsuccessfully to theorize the professions in a way that would include engineers. The problem was that engineers tended to work within large organizations. Separate career ladders for engineers were unpopular, and success for more elite engineers entailed success within the organization. Also, as recently as the mid-1950s, nearly one-tenth of the U.S. engineering labor force of 500 000 was unionized, with organizational concerns emphasizing salary levels and work

conditions. For American sociologists, examining engineers more closely actually contributed to a more general disciplinary shift to organizational studies.

In the mid-1980s, Robert Zussman (1985) unsuccessfully tried to revive sociological interest in engineers by examining them through the lenses of career and class rather than profession. The normative commitment of engineers to career mobility by changing jobs, he argued, could be traced to their middle-class status. But this move did not overcome the continuing problem that engineers faced in their effort to claim autonomy and normative holism for their profession while pursuing advancement within organizations.

Some Anglo-American historians of engineering implicitly accepted the assertion that engineers serve humanity as a whole by examining the organization of professional societies and professional institutions and their recruiting initiatives among students. Many historians, however, have long questioned the role of normative holism in the formation of the engineering profession precisely by calling attention to the way engineers were positioned within organizations. A few elite civil engineers in the late nineteenth-century United States did achieve a public reputation bordering on heroic status. The vast majority of U.S. engineers, even civil engineers on commission, had almost always been supervised within, while serving the interests of, governing organizations. Also, would-be professional engineers coexisted in the United States with a much larger number of nonprofessional engineers. Edwin Layton's *Revolt of the Engineers* traced a transitional process through which the leaders of professional engineering societies tended also to become leaders of industry. Peter Meiksins (1988) later showed that Layton's account masked struggles of rank-and-file engineers whose concerns were less about professional recognition and autonomy than humane employment and chances for promotion.

Taking a lead from the engineers' commitment to serving humanity as a whole, applied philosophers have devoted enormous effort to interrogating ethical tensions between normative holism and organizational loyalty. Early contributions explored engineers' rights and responsibilities as employees, examined the role of ethics training in engineering curricula, and assessed formal codes of ethics. I cannot do justice in this article to the evolution of research on engineering ethics over the past three decades. See Mitcham (2010) and Barry and Herkert (2014) for starting points.

The bottom line is that engineering studies scholarship has challenged the implication of normative holism that engineers are or should be treated as autonomous professionals. Explicitly positioning themselves within engineering studies, sociologists Carroll Seron and Susan Silbey (2009) showed that the U.S. accreditation process for engineering curricula enacts an instrumental logic that restricts the discretionary judgment characteristic of professions. Professional focus amounts to making sure engineering students master the instrumental logic.

Research in engineering studies that draws on the image of profession may challenge engineers to look past the bounded considerations of employees to consider identities focused on broader commitments. It points researchers in the direction of supporting or helping to create courses, curricula, and institutions devoted to making visible the involvement of engineers in issues such as climate change, water supply and usage, energy supply and usage, and so on. Critical participation of this sort can help students recognize and reflect on normative commitments implicitly built into existing curricula, e.g., that a key future responsibility will be to support the private interests of an industrial employer.

At the same time, work that judges engineering practice in relation to an image of the profession, whether explicitly or implicitly, may limit the ability of curricular interventions to move beyond the periphery of the new course, specialized track, or voluntary membership organization. The image of a profession serving humanity as a whole does not fit much of what engineers actually do.

For Private Industry?

That engineers in, especially, Anglo-American contexts have accepted private industry as the dominant venue for their work has been a primary source of interest and concern for engineering studies research on engineering formation. Monte Calvert (1967) famously attributed the bonding of mechanical engineers to industrial organizations to a contingent shift in educational practices from 'shop culture' to 'school culture.' This shift greatly expanded attention to formal education, especially at land-grant institutions. While mechanical engineers had been elite apprentices engaged in on-the-job preparation for leadership positions, they became tertiary school graduates prepared for entry-level positions and armed with a desire to move up the corporate ladder.

Are engineering students preparing to be servants of industrial corporations? David Noble (1977) put the issue most starkly in a classic Marxian study loaded with evidence about the emergence of engineering formation in the United States. He argued that normative holism was essentially false consciousness, because engineering education served as "a major channel of corporate power" (p. 47) by providing the "immediate manpower needs of industry and the long-range requirements of continued corporate development" (p. 170). Its output was a "domesticated breed" (p. 322) that "convinced themselves that they served the interests of society as a whole … [but] in reality served only the dominant class in society" (p. 324).

The influence, if not control, of normative projects from private industry remains a contentious issue in engineering studies. Many reactions have challenged the claim of domestication. How, for example, does one view capitalist relations of production as deterministic while also calling attention to historical contingencies that point engineers in a variety of directions (Meiksins and Smith, 1996)? Studies based in the United Kingdom have wrestled with such issues as employer scorn for formal engineering education, relative disinterest by government agencies, tension over the continuing role of craft training, and workers managing dual commitments inside and outside of industrial organizations. A surge of engineering studies scholarship on engineering work carried forward the normative questions and their implications for technical–social dualism. Anderson et al. (2010) documented the frustrations of engineers who tried to bring technical–social dualism onto the job and then

found that their actual responsibilities did not fit it. Gainsburg et al. (2010) found that workplace knowledge and commitments in an engineering occupation may derive more from on-the-job experience than from prior formal education. Meanwhile, Will-Zocholl and Schmiede (2011) argued that globalized work that was reliant on information technologies tended to marginalize purely technical tasks.

Taking the relationship between the formation of engineers and private industry as one's primary objective of study has different implications depending upon how one theorizes that relationship. David Noble's analysis of engineers as a breed domesticated by the dominant class depended upon his view that capitalism invariably produces exploitation of labor. Studies like Noble's which assume that class inequalities are structured by capitalism channel critical participation into revolutionary action; action that promises to transform engineers into an entirely different breed altogether, not to mention all of social life as well. The position effectively accepts resolute pessimism about changing the existing state of affairs.

Any alternatives ultimately require questioning the Marxian labor theory of value. Peter Lundgreen (1990), described below, articulated one prominent project that focused on the state rather than capitalist industry. Other approaches might build on the view that the labor theory of value insufficiently considers the range of normativities in industrial production, as well as the distinct roles of different technological agencies. Pursuing such agencies would require defining pathways for critical participation within the firm. In any case, Noble's thorough and consistent analysis continues to throw down a gauntlet that any research or attempt at critical participation through engineering studies ignores at its peril.

For Technology through Design?

An integral component of the engineer's commitment to humanity as a whole is that engineers learn their disciplines in order to design technologies. It is their real work. The flow is linear and the emphasis is technical. Much scholarship in engineering studies has problematized this flow by complicating each step.

Philosophers of technology have long wrestled with how engineering and the applied sciences manage distinctions between epistemic sources and technological outputs. Adopting normative stances that epistemic categories were freed from context, philosophers of technology in the 1960s debated whether the most important epistemological distinction in engineering was between pure and applied science or applied science and technology. One key outcome of this debate was the rise of interest in a philosophy of engineering.

Philosophers of engineering have tended to start with epistemics and then identify links to broader social projects that contribute to the actual identities of engineers. Walter Vincenti (1990) did not venture beyond epistemics when he posited universal, context-free categories of design knowledge, including fundamental design concepts, criteria and specifications, theoretical tools, quantitative data, practical considerations, and design instrumentalities. Positing context-free categories facilitated a continuing, implicit commitment to normative holism. Others maintained that the societal positioning of engineers as technological intelligentsia or of engineering as an occupation required one to plot the epistemological contents of engineering work in relation to a range of social and ethical contents and dimensions.

Questioning the linear thread from the engineering sciences to their jurisdiction over technology led researchers to also examine normativities in engineering design. Larry Bucciarelli (1994) found that engineering designers work in object worlds with distinct material commitments. Many philosophers emphasized that engineering design should be situated in context, introducing extraepistemological issues such as ethical ambiguities; diverse user perspectives; variable legal commitments and implications; and a variety of financial, environmental, and aesthetic considerations. Helpful starting points include Christensen et al. (2009) and van de Poel and Goldberg (2010).

Actor-network theorists examined design practices as themselves sources of broader material projects. John Law and Michel Callon (1988) portrayed practitioners in engineering as engineer-sociologists who become social activists by designing both machines and their social institutional contexts. Dominique Vinck, Eric Blanco, and colleagues (Vinck and Blanco, 2003) showed how engineering design practices organize things and people at the same time.

Finally, some scholars in engineering studies have examined frictions or discontents produced by competing claims of jurisdiction over technology itself. Matthew Wisnioski (2012) traced how the assumption that engineers enjoyed such jurisdiction encountered a crisis in elite engineering circles during the 1960s when technology itself lost its assumed link with progress. Gary Downey (1998) showed how engineering students and practitioners who sought control over computer-aided design technologies in the 1980s found that they also had to yield to them. Rosalind Williams (2002) explored how attempting to control increasingly diverse technologies during the 1990s threatened to produce an 'expansive disintegration' of engineering research and teaching.

The image of engineering in context fuels numerous projects that attempt to foster critical participation in the making of engineers and engineering practice. It is relatively straightforward to demonstrate to would-be engineers that they will have to participate in a variety of social contexts, including relations with employers, fellow employees, clients, professional associations, standards organizations, regulatory bodies, and so on. And making such contexts visible can help students recognize that technical problem solving will be only part of what they do and that they would do well to prepare for participation in a variety of contexts.

A difficulty facing this approach is that it risks leaving untouched the technical–social dualism that normative holism presumes and supports. This difficulty arises when *context* comes to refer to everything that does not have to do with the linear flow of technical practices from engineering science through design to the production of technology. The challenge is to take account of how engineers are already, as Wisnioski puts it following Bruno Latour, contextualizing themselves in their commitment to normative holism and technical–social dualism.

For the Nation, State, Country?

Peter Lundgreen's (1990) contribution to studies of normative projects in engineering resisted the image of the field as a response to the needs or demands of private industry. Lundgreen highlighted the way French engineers, since the eighteenth century, were committed to training through schools and government projects. The emergence of engineering education across Germany during the nineteenth century also could not be attributed simply to private sector needs. By emphasizing agencies of the state, Lundgreen called for research into how practices of supplying engineers go beyond responding to needs or demands, thus distinguishing between commitments in qualifying engineers and in putting them to work.

Enormous bodies of work now exist in histories of the development of engineering in different countries. Detailing what Antoine Picon (2007) called 'local specificities,' these works integrate histories of the formation of engineering with histories of the development of nation-states. Some studies presented engineers as developing distinct engineering 'styles' that 'reflect' or 'reinforce' host national cultures or grammars.

The most common form of analysis is to recount the relative role of state authority in both institutional and curricular developments in engineering education. I can provide here only starting points. Antoine Picon (1992) explained how eighteenth-century engineers overtook architects by acquiring quasi-judicial authority as they pursued technocratic ideals. Bruno Belhoste and Konstantinos Chatzis (2007) reviewed the preparation of state engineers in nineteenth-century France. Contributors to an edited volume by Ana Cardoso de Matos et al. (2009) examined how models for training engineers were disseminated, focusing on the role of key reference schools, and the distinctive normative programs in schools on the European periphery. Such interests in efforts to theorize appropriation, circulation, and transnationality have extended worldwide.

As should be clear by now, this article is informed by an approach that critiques normative holism and technical–social dualism. However, this approach is not only a matter of unmasking what the holistic and dualistic ideology hides, but is instead a matter of demonstrating multiplicity in the forms and formations of engineering. What has counted as progress or human advancement has varied dramatically across territories and over time. One reason why some scholars identify distinct cultural practices of engineering education and training is that such locates the technical contents of engineering in the same analytical and ontological category as practices of governmental action, political economy, higher education, activities of work, etc. They all become cultural phenomena. However, this point also presents a key challenge. Engineers tend to use 'culture' as a label that covers everything that is not technical, hence not authentic engineering. Attempting to persuade engineers that the technical contents of engineering are cultural may appear to remove technical rigor from engineering judgment and throw up a barrier to significant critical participation.

Documenting the role of the state in the making of engineers could, in principle, motivate critical participation in the operations of the state. The difficulty lies in accepting the multidimensional challenges of participating in governmental action at the national level. Studies of engineering which demonstrate that there are multiple versions of normative holism and technical–social dualism can inform those who educate and train engineers that what they take for granted is highly localized. A longer-term possibility is that of teaching engineering as a matter of both problem definition and solution, positioning every course and pedagogical practice as a normative project that makes some things visible and doable while hiding others (Downey, 2009). A limitation is that persuading engineering instructors to carry the vision of engineering as problem definition and solution to the heart of their pedagogical practices may require something akin to a mass social movement in engineering instruction.

For Gender, Racial, Heterosexual, Developmental Privilege

Numerous critiques of normative holism and technical–social dualism make visible other material normativities in engineering formation and engineering practice. Important areas explored to date include gender, racial, and heteronormativities, as well as issues of social justice in international development.

Extending Sally Hacker's (1989) early work on the masculinization of technology and technologists, Ruth Oldenziel (1999) found that the professionalization of engineering was a project that turned out to be a thoroughly male and middle-class endeavor. Karen Tonso (2007) showed how practitioner identities at an engineering school did not include women. Wendy Faulkner (2009) explored how engineering identities were congruent for men but not for women.

Race and sexual orientation have received less attention. Amy Slaton (2010) examined how conceptions of engineering talent and rigor have supported racial selectivity in U.S. engineering schools. Erin Cech and Thomas Waidzunas (2011) showed how mechanisms of heteronormativity produce experiences of marginalization and isolation for lesbian, gay, and bisexual students.

A fast-growing research area in engineering studies involves the way the involvement of engineering in industrial development has contributed to increased inequality and social injustice. Dean Nieusma and Donna Riley (2010) demonstrated how the priority accorded to final products in engineering for development could not only accentuate existing power asymmetries but also generate wholly new ones. For many more examples, see the sizable collection of volumes on engineering and social justice in the Synthesis Lectures on Engineers, Technology, and Society at Morgan and Claypool Press, edited by Caroline Baillie.

It is essential for engineering students and engineers to understand the workings of power and privilege in engineering, so that they can recognize the limitations in normative holism and technical–social dualism. Engineers and nonengineers who are disempowered or made invisible by dominant images of engineering can find lifelines and encouragement in critical analyses of sources of privilege in engineering. Engineers who learn how they benefit from privileges they did not earn cannot easily assert that engineering always serves humanity as

a whole. Understanding what dominant images hide is the first step in formulating alternatives. A significant challenge lies in carrying critique from the periphery into critical participation at the center. What would it take for routine pedagogy in engineering to make explicit the sources of gender, racial, heteronormative, and developmental privilege? What more must be learned about the barriers posed by normative holism and technical–social dualism in order to alter them?

What Is the Field of Engineering Studies for?

In his 1954 novel *The New Men*, C.P. Snow (1961[1954]: p. 176) blurred the two cultures of science and the humanities when he characterized engineers. "[E]ngineers," he wrote, "… were in nine cases out of ten … acceptant of any regime in which they found themselves." Although it is fiction, this characterization of engineers still stands out because it likely strikes the vast majority of readers as true. The key question it raises is: Why?

If engineers are bred to be wholly domesticated agents of powerful external forces, engineers are weak and their acceptance of the regime in which they find themselves is a kind of surrender. From this point of view, it makes little sense for critical scholars to go beyond critique to seek critical participation. Their work will be co-opted. The situation changes, however, if engineers are in a regime because they accept it; because, to paraphrase Snow, they are mainly interested in making their machines work and the regime facilitates that end. In that case, multiple normativities in engineering are more interestingly situated alongside its multiple epistemological and ontological contents. Initiatives to participate critically in engineering formation and practice also become more than exercises in engagement: they are sites for research, for expanding critical understandings of engineers and engineering. Critical participation in the service ideals and assumptions of engineering generates localized knowledge about the scope, operations, and accountability of engineering.

The questions – what is engineering for, and what are engineers for? – have guided engineering studies work. Yet the dominance of the images of normative holism and technical–social dualism means that no researcher in engineering studies can escape the additional question: What is engineering studies for?

Abstract

The two decades from 1640 witnessed unprecedented change in England, including civil war between king and parliament, the trial and public execution of the king, and the abolition of monarchy. The term 'the English Revolution' has often been applied to this period, and the revolution has been portrayed as a forerunner of the eighteenth-century American and French revolutions. Many historians and other scholars working on the period have, however, doubted whether a revolution actually occurred in these years. This article explores the range of scholarly approaches to the period 1640–60 and suggests that in the realm of ideas, at least, we can see a revolution having taken place.

On 13 April 1640, an English parliament assembled at Westminster for the first time since 1629, at the end of the 11-year period of 'personal rule' when King Charles I had attempted to rule without the assistance of parliaments. The Short Parliament of 1640 sat for just 3 weeks before it was dissolved, but the parliament which gathered early in the following November was to sit uninterrupted until 1653. While this, the Long Parliament, was in being, England experienced prolonged periods of civil war and unprecedented political change. War between king and parliament broke out officially in August 1642, when Charles raised his standard at Nottingham. The first civil war concluded in 1646 with the defeat of the king's forces, but after a second civil war in 1648 parliament was purged of those MPs who had wished to continue negotiations with the king, and Charles was put on trial and convicted as a traitor to the people of England. In the months following the king's public execution on 30 January 1649, parliament legislated to abolish the monarchy and House of Lords, and England was declared to be a commonwealth and free state, to be governed by a unicameral parliament and council of state. The army, under the command of Oliver Cromwell (1599–1658), launched a bloody conquest of Ireland in the summer of 1649, and in the following year his forces invaded Scotland and, on 3 September, resoundingly defeated the Scots at the battle of Dunbar.

Relations between the army and parliament became increasingly fraught, and on 20 April 1653, Cromwell brought troops to Westminster and expelled the MPs. Power now resided with Cromwell and the army. In June, an assembly, made up of nominated rather than elected members, met at Westminster and soon declared itself to be a parliament. This assembly, which was popularly known as Barebone's Parliament, continued to sit until December, when, as a result of conflicts between its radical and more conservative members, it surrendered power back into the hands of Cromwell. Later that month, Cromwell was named Lord Protector of the Commonwealth of England, Scotland, and Ireland, his powers limited and defined by the Instrument of Government, England's first written constitution, which had been drawn up by some of Cromwell's closest supporters. The office of Lord Protector was to be elective rather than hereditary, and executive power was to be in the hands of a permanent council of 21 members. There was provision for triennial parliaments, and a system of checks and balances was intended to ensure that decision making on the important issues of war, finance, and appointment to senior offices could be shared between Protector, council, and parliament.

In 1655, frustrated by the slow process of godly reform, and in the wake of a series of royalist risings, Cromwell introduced the 'Rule of the Major-Generals,' in which England and Wales were divided into 10 regional associations, each presided over by a major-general. The major-generals were charged with maintaining security, upholding law and order, and advancing godly rule in the provinces. The scheme was to be financed by a decimation tax imposed on former civil war royalists, including those who had made their peace with the regime. Opposition to 'swordsmen and decimators' was a marked feature of the elections to the second Protectorate Parliament in 1656, and the major-generals scheme was abandoned after the militia bill, which would have placed the decimation tax on a permanent footing, was decisively voted down on 29 January 1657. In the following month, parliament presented Cromwell with the Humble Petition and Advice, a new draft constitution which sought to address what were seen as the limitations of the Instrument of Government. Cromwell was offered the crown, and provision was made for a second parliamentary chamber, or 'Other House.' It was not until May that Cromwell refused the offer of the crown, but a modified Humble Petition was accepted, with Cromwell being given the power to nominate his successor. Cromwell died on 3 September 1658, and was succeeded as Protector by his son Richard (1626–1712). His period of rule lasted only until the following May, when the Protectorate was swiftly brought to an end. Friction between the army and parliament had led to the dissolution of the third Protectorate Parliament in April 1659, and to the return on 7 May of the 'Rump' of the Long Parliament; with the Rump re-installed, Richard Cromwell had little option but to resign from office. The Rump remained in power until October, when it was expelled by the army, and there followed 2 months of rule by an army-backed committee of safety. After General George Monck, commander of the English forces in Scotland, declared in favor of parliament, the Rump was allowed to return and it met again on 26 December 1659. In January,

Monck marched into England, and arrived in London the following month. His decision to support the return to parliament of MPs secluded in the purge of December 1648 made the return of monarchy inevitable. The Long Parliament dissolved itself on 16 March 1660, and the Convention which followed invited Charles Stuart, son of the executed Charles I, to return to England as king. By many accounts, the revolution that had begun in 1640 was now at an end.

Historians have long argued over the significance of the events of the two decades from 1640 to 1660 and over whether they can actually be said to constitute a revolution. The term 'revolution' was of course in use in the seventeenth century, but its meanings were rather different from our modern understanding of the term (Snow, 1962; Harris, 2005: pp. 32–37). The events of 1640–60 were more often than not described as 'the Great Rebellion,' 'the Usurpation,' or 'the Troubles.' When more modern, and more precise meanings of the term revolution came into fashion, the term tended to be used to describe the events of 1688–89, when the rule of James II and the Stuart dynasty ended, rather than the mid-century events. For many years it was this 'Glorious Revolution' that was seen to constitute England's sole modern political revolution. The French Revolution of 1789 led to a reappraisal of the nature and significance of England's mid-seventeenth-century conflicts, and it was in France rather than England that 1640–60 first came to be identified as a period of revolution. It is usually thought that the first thinker to call the events of 1640–60 'the English Revolution' was the French politician and historian Francois Guizot (1787–1874), the first volume of whose *Histoire de la révolution d'Angleterre* appeared in 1826 (Guizot, 1826–27). It is, however, known that earlier French revolutionaries, recognizing the striking similarity between events in England in the 1640s and events in France after 1789, were in the 1790s already referring to 1640–60 as 'la Révolution Anglaise' (Hammersley, 2010: pp. 159–161). Guizot, moreover, never saw 1640–60 as a single, discrete revolution, but rather as part of a longer process of revolution which began in 1640 and culminated in the Glorious Revolution of 1688–89. For him, the English Revolution comprised 'three grand periods,' namely 1625–49, 1649–60, and 1660–88. It was, he maintained, only in 1688 that "England achieved the point she aimed at in 1640" (Guizot, 1846).

Karl Marx, despite his strong antipathy to Guizot the politician, was heavily influenced by his interpretation of seventeenth-century English history. Marx, as is well known, advanced the notion that England experienced a bourgeois revolution in the seventeenth century, and maintained that the English Revolution was among the most significant of such events. Both Karl Marx and Friedrich Engels acknowledged the interest and importance of what had taken place in the two decades from 1640, but they did not, as is often assumed, see the period 1640–60 as in itself a major turning point in English history. For Marx and Engels, like Guizot before them, the seventeenth-century English Revolution was a much longer process, one that began in 1640 and concluded only in 1688–89. The latter date was at least as significant as 1640 or 1649: it was then that 'the bourgeois transformation of English society' was accomplished and 'the first decisive victory of the bourgeoisie over the feudal aristocracy' achieved (Marx, 1979: p. 105; Pincus, 2009: p. 34). Eduard Bernstein was following established Marxist usage when he later described the revolution of 1688 as the 'last phase' of the English Revolution (Bernstein, 1930: p. 10).

It was the great Victorian historian S.R. Gardiner (1829–1902) who, in the 1880s and 1890s, was primarily responsible for focusing attention once more on 1640–60. Although he never lost sight of the longer perspective, he came to regard the two decades from 1640 as a period of revolution in its own right. In his Rankean multivolume histories of the period, which laid the foundations of modern scholarship on mid-seventeenth-century England, Gardiner adopted the term 'the Puritan Revolution' to describe the events of 1640–60 (Richardson, 1998: pp. 91–96; Worden, 2001: p. 270). Gardiner was – as his chosen term suggests – aware of the crucial importance of religion to the revolution, but much of his explanatory focus, like that of so many of his predecessors, was on issues of constitutional conflict. Earlier 'Whig' historians, like T.B. Macaulay (1800–59), had argued that the civil wars of the 1640s had been preceded, and brought about, by worsening relations between Crown and Parliament. For Macaulay, the blame lay squarely with the first two Stuart monarchs, James I and Charles I, who were accused of blindly pursuing absolutist policies, shored up by high-flown notions of 'divine right.' James was, for Macaulay, clearly "one of those kings whom God seems to send for the express purpose of hastening revolutions" (Macaulay, 1843: p. 435). It was Macaulay's contemporary Thomas Carlyle (1795–1881) who in his edition of *Oliver Cromwell's Letters and Speeches* (1845) fully grasped the importance of religion to the mid-seventeenth-century conflicts and captured the puritan spirit at the heart of the parliamentarian movement (Worden, 2001: pp. 269–277).

The high standards set by Gardiner were continued in the work of his close friend Sir Charles Firth (1857–1936), the author of major histories of the period and editor of significant memoirs and other collections of primary sources. Much of the focus of research in the first half of the twentieth century, particularly in the United States, was on early-Stuart parliamentary history and constitutional conflict. Among the most significant works to appear was Wallace Notestein's published version of his 1924 Raleigh Lecture, 'The winning of the initiative by the House of Commons' (Notestein, 1924), a work that had a tremendous influence in the field, and which too often came to be read without due attention to the qualifications that hedged the author's arguments about the rise in influence of the Commons (Russell, 1990: pp. 33–34). It was in 1940 that a startlingly new interpretation of the period 1640–60 appeared, in the work of the young Marxist historian Christopher Hill. In his contribution to his edited collection marking the tercentenary of the revolution, Hill boldly announced that "the English Revolution of 1640–60 was a great social movement like the French Revolution of 1789." The old, essentially feudal order was destroyed in a struggle waged by the bourgeoisie and progressive gentry, and 'a new and capitalist social order' was created in its place. The Restoration of 1660 was, he insisted, "by no means a restoration of the old order" (Hill, 1940: pp. 9, 13, 76). Hill's interpretation was a Marxist one, but one that was indebted less to Marx than to recent developments in Soviet

historiography. Just as Marxist and Marxist-influenced scholars in France had come to present the French Revolution as a necessary forerunner of 1917, so the English Revolution could be portrayed as one that anticipated the French and was comparable in its significance. The English had, it seemed, got there first. While Marx and Engels had always recognized the significance of 1688–89 as the point when England's bourgeois revolution reached its successful conclusion – the moment, as Marx remarked, when "Locke supplanted Habakkuk" (Marx, 1979: p. 105) – Hill argued that 1688 was little more than an afterthought, and that the crucial changes which might define a bourgeois revolution had taken place in England by 1660. England's eighteenth-century commercial prosperity, Hill maintained, derived from the Navigation Act of 1651, and this act, together with the sale of royalist lands, the ending of monopolies, the dismantling of the courts of Star Chamber and High Commission, and the abolition of feudal dues for landowners (though not, significantly, for their tenants) all combined to ensure that England's bourgeois revolution should be seen to have occurred in 1640–60 (Hill, 1940: pp. 70–71, 74–79). In his focus on 1640–60 at the expense of 1688, Hill was clearly following the lead set by Gardiner, but Gardiner's Puritan Revolution had now given way to a determinedly Marxist bourgeois revolution. In the years that followed, Hill's thesis shifted somewhat – the revolution was no longer said to have been consciously willed by a rising bourgeoisie – but his argument about the revolution's outcome remained essentially the same: the most significant impediments to capitalist development had, he insisted, all been removed in the revolutionary decades (Hill, 1980: pp. 134–135). The term 'the English Revolution' as a descriptor of the events of 1640–60 soon gained general currency, among Marxist and non-Marxist scholars alike. Only a few scholars held out against the adoption of the term, preferring instead to continue to refer to 'the Great Rebellion,' 'the Puritan Revolution,' or 'the Civil Wars.'

Hill was not alone in the 1940s in advancing a social interpretation of the revolution. In 1941, in the year following the publication of Hill's *English Revolution 1640*, there appeared R.H. Tawney's 'The rise of the gentry, 1558–1640,' which sought to demonstrate that a shift in the balance of property, from the nobility to the gentry, had occurred in the century before the civil war. Tawney's arguments, which appeared to many to confirm the philosopher James Harrington's belief that the civil wars and the breakdown of the old order were linked to long-term shifts in property holding, were for a time highly influential, and were soon supported by the work of the young historian Lawrence Stone. A formidable assault on Stone and Tawney was mounted in 1951 by Hugh Trevor-Roper, who argued that significant sections of the gentry were declining rather than rising in the years before the civil war, and that it was from among this group that a 'country' opposition, which was to rise up in rebellion and eventually defeat the king, drew its most vigorous supporters. Trevor-Roper's arguments were no less speculative than those of his opponents, but his demolition of the 'rising gentry' thesis was supported by detailed research by, among others, the historian J.P. Cooper. The so-called 'gentry controversy' continued on its destructive course for several years before petering out inconclusively, its main protagonists having withdrawn to heal their wounds or having moved on to less controversial areas of research (Richardson, 1998: pp. 116–121).

By the later 1960s, many of the old certainties had gone, without having been replaced by any new consensus. A bold attempt to offer a convincing and holistic explanation of the causes of the English Revolution was provided by Lawrence Stone in 1972. His work drew on research into other great revolutions, and on current sociological theory, as well as the most recent research into seventeenth-century British history, and he combined discussions of the typology of revolution with attempts to distinguish clearly between the preconditions, precipitants, and triggers of England's revolution. There was no doubt in Stone's mind that the English Revolution of 1640–60 was a genuine revolution, its revolutionary nature clearly demonstrated in both its deeds and its words. Stone's thesis was by no means a Marxist one, and he made clear his doubts about the applicability of 'the class war theory of the Marxists' to the seventeenth century (Stone, 1972: p. 54). In the same year, however, as the publication of Stone's *The causes of the English Revolution*, there appeared an even more influential work by the veteran Marxist historian Christopher Hill. Hill's *The World Turned Upside Down* focused on the radical fringe of the 1640s and 1650s, what Hill called the "revolt within the revolution." This was, for Hill, the radical revolution that threatened, but never quite managed, to take England's successful bourgeois revolution forward in unexpected directions. Hill's book, which was reissued 3 years later as a mass-market paperback, caught the counter-cultural spirit of the moment, and had an influence well beyond academia (Hill, 1972; Gurney, 2013: pp. 7–8, 123–124). Much of Hill's research in the 1950s and 1960s had focused on the relationship between puritanism, society, and literature in seventeenth-century England; his new, and widely read study of the prophets, radicals, and 'masterless men' of the revolutionary decades seemed to many to offer something more exciting: a radical history-from-below, one that demonstrated the truly revolutionary potential of the events of 1640–60. Just as Hill had sought in 1940 to prove that England had experienced a genuine, and successful revolution in the mid-seventeenth century, *The World Turned Upside Down* helped remould and revivify that revolution for a new generation (Reay, 1988: pp. 53–71).

Among the new generation of historians who came to prominence in the late 1960s and 1970s, many were unconvinced by conventional Whig and Marxist interpretations of seventeenth-century history, and they were impatient to tackle these head on. Although Christopher Hill retained widespread, though not universal, respect among younger historians, his broad arguments and conclusions were seen by many of them to be unpersuasive. Other scholars – many of them based in the United States – whose work continued to focus on long-term constitutional changes and on clashes over constitutional principle, were also found wanting. The greatest hostility was, however, directed against historians who aimed at providing overarching explanations: Stone's *The Causes of the English Revolution* was a particular target of the new generation (Morrill, 1993, 1999: p. 276, pp. 5–10). In place of ambitious attempts at synthesis, there appeared a plethora of influential works on a variety of subjects, united principally by their questioning of old certainties, their unraveling of long-accepted explanations,

and their drawing on sources that had been unavailable to, or largely ignored by, the older generation. The label loosely applied to these historians, and happily taken up by many of them, was 'revisionist.' The revisionists sought both to demolish the old edifice and rebuild afresh, but the rebuilding often proved more difficult than the initial act of demolition.

Some of the most significant research undertaken by revisionist historians addressed early-Stuart parliamentary history. Kevin Sharpe's *Faction and Parliament* was a key revisionist text, a collection of essays that challenged assumptions about the existence of binary divisions between government and opposition in pre-civil-war England, and drew attention to the politics of faction and interest in the workings of Stuart parliaments (Sharpe, 1978). The most influential critic of traditional accounts of pre-civil-war parliamentary history was undoubtedly Conrad Russell, whose searching 1976 essay 'Parliamentary history in perspective' did more than any other piece of work to undermine the assumption that Parliament, and particularly the House of Commons, was engaged in a long-term pursuit of power and was the main center of 'opposition' to the Crown. His *Parliaments and English Politics*, a forensic study of the parliaments of the 1620s, followed in 1979 (Russell, 1979, 1990: pp. 31–57). Mark Kishlansky's work on the emergence of adversary politics in the Long Parliament, and his important monograph on the rise of the New Model Army, helped do for the 1640s what Russell had done for the 1620s, questioning long-cherished assumptions about the nature of parliamentary politics and political divisions at the height of the civil wars (Richardson, 1998: pp. 222–223; Kishlansky, 1979).

Traditional arguments about the rise of Puritanism, which had featured so strongly in the older social interpretations of the English Revolution, also came under sustained attack at this time. Nicholas Tyacke's work on Arminianism challenged long-held views about the impact on the Church of England of an aggressive and increasingly self-confident Puritan opposition. Tyacke instead drew attention to the Calvinist consensus that lay at the heart of the early-Stuart Church, one that was, he argued, broken by the divisive policies pursued by Archbishop Laud and his allies. It was an Arminian rather than Puritan revolution that provoked instability in the Church: Charles and Laud were the true religious innovators (Tyacke, 1973: pp. 119–143). William Lamont's groundbreaking work on millenarianism, which succeeded in rescuing it from the radical fringe and restoring it to its central place in mainstream Protestant theology, also helped to undermine the notion that the causes of the conflicts of the 1640s were inextricably linked to the rise of revolutionary Puritanism (Lamont, 1969). J.C. Davis's forensic analysis of the nature of early modern radicalism also forced scholars to rethink what they had previously so often taken for granted (Davis, 1982, 1992). Together these works drew on, and contributed to the development of, the new approaches to early modern intellectual history pioneered by J.G.A. Pocock in his *The Ancient Constitution and the Feudal Law* (Pocock, 1957).

Detailed empirical research was a marked feature of revisionism. Blair Worden's *The Rump Parliament*, which drew attention to the limited ambitions of the participants in the revolutionary changes of 1648–49, and the unplanned and unexpected nature of events, displayed a command of the sources of which Gardiner and Firth would have been proud. Few of the MPs who remained at Westminster after Pride's Purge, or who returned in the months following the execution of the king, could, Worden demonstrated, be described as republicans. Many of them followed events rather than shaping them, and their continued participation in Westminster politics was as much about staving off military rule as about condoning the revolutionary developments of 1648 and 1649 (Worden, 1974). One area of research most closely associated with revisionism was the study of local society and relations between center and locality; several important county studies, among them Alan Everitt on Kent, John Morrill on Cheshire, and Anthony Fletcher on Sussex, appeared in the late 1960s and 1970s. Much of the focus of these studies was on the workings of the 'county community' and on the strengths of localist mentalities: for Everitt, England in the first half of the seventeenth century could plausibly be seen as a union of partially independent county-states, and the interests of the county often came before the interests of the nation. Not all of the county community historians went so far as Everitt, but cumulatively their work helped to complicate traditional narratives and undermine further the sense that battle lines across the nation had been drawn up well before the outbreak of war in 1642. There was also general consensus among county community historians that the success of Parliament in the civil war was due in part to its ability to override local sensibilities, its centralizing actions provoking further localist discontent.

Revisionist scholarship transformed understandings of the causes and nature of the conflicts of the revolutionary years. Teleological explanations were jettisoned, detailed empirical research opened up new areas of study, and the contingent nature of events was always emphasized. Nothing could be taken for granted any more, and it no longer seemed possible to fall back on the old social interpretations, or on interpretations that emphasized long-term constitutional or religious conflict, to explain the origins and course of the revolution. But the field of English Revolution studies was becoming a fragmented one, and the explanatory frameworks now adopted by historians would often appear more suited to showing what had not happened than what had. Older historians like Christopher Hill lamented the failure to replace discarded theories with any more persuasive replacements: during the 1980s Hill, placing his hopes as much in a younger generation of literary scholars as in historians now working on the seventeenth century, regularly called for the development of a 'new synthesis.'

Others too picked up on what they saw as the limitations of the revisionist approach. The American historians J.H. Hexter and Theodore K. Rabb both restated their belief in the centrality of parliament and its increasing importance in early-Stuart England. They were unconvinced by revisionist attempts to downplay parliament's importance, or to portray it as merely an irregular event rather than an institution, with only a peripheral role within government. For Rabb, the picture presented long ago by Gardiner was a remarkably durable one, and was in need rather of modification than abandonment (Hexter, 1978; Rabb, 1981). Derek Hirst joined these critics of

revisionism in arguing for the central importance of constitutional principle in shaping parliament's, and the wider public's, attitude to the Crown in the years before 1640 (Hirst, 1981). The 'county community' historians also came in for vigorous criticism, with Clive Holmes insisting that "the preeminence of local allegiance and the gentry's ignorance of, and lack of concern for national issues, goes beyond the evidence" (Holmes, 1980).

The need to replace older narratives of the English Revolution with more convincing new ones was addressed by a group of younger historians to whom the label 'postrevisionist' was often applied. The postrevisionists accepted many of the criticisms that revisionist historians had leveled against their predecessors, but argued that at too many points the revisionists had gone too far. In particular, they accused revisionists of exaggerating levels of political and religious consensus in pre-civil war England, and of ignoring or downplaying the plentiful evidence that existed of conflictual relations in church and state in the early-Stuart period. Their rallying-cry came in the influential volume *Conflict in Early Stuart England*, a volume of essays edited by Ann Hughes and Richard Cust which sought to demonstrate the ways in which significant religious and political divisions had emerged over the course of the sixteenth and early seventeenth centuries, and how ideological positions had hardened in this period. Such developments did not make the civil conflicts of the 1640s inevitable, but they could certainly help to explain why any pursuit of settlement in 1640–42 would have had little chance of success (Cust and Hughes, 1989).

New perspectives were also offered on the question of popular political consciousness. Historians like John Morrill and David Underdown, driven partly by their disquiet at what they saw as Christopher Hill's tendency to too readily equate the radical with the popular, had already sought to explore popular, non-radical responses to the burdens of civil war in the 1640s. Postrevisionists began looking afresh at the ways in which the spread of news and political ideas could influence the thinking of those below the gentry, and at how people were able to make positive political choices, independent of gentry leadership, at crucial moments (Cust, 1986). In some respects this work picked up from that of older historians like Brian Manning, whose *The English People and the English Revolution*, which had received a cool reception from revisionist historians, had sought both to place popular agency at the heart of 1640s politics and to demonstrate the ways in which a 'popular' movement had helped shape political developments in those years (Manning, 1976). Later work by historians such as John Walter, David Underdown, and David Cressy, would add immensely to understandings of popular responses to, and involvement in, political developments in the revolutionary decades (Walter, 2006; Underdown, 1985; Cressy, 2006).

Perhaps the most significant reappraisal of civil war history came from two historians who had long been associated with revisionism, John Morrill and Conrad Russell, who quite separately began exploring the *British* dimension to England's mid-century struggles. Drawing on J.G.A. Pocock's influential call for the creation of a new British history, Russell and Morrill both argued that England's civil war and revolution could not properly be understood independently of events elsewhere in the Atlantic archipelago. Charles I, as King of England, Ireland, and Scotland, was faced with immense, and possibly intractable, problems as ruler of multiple kingdoms. Conflicts in one kingdom invariably affected and became intertwined with developments elsewhere (Russell, 1990: pp. 231–251; Bradshaw and Morrill, 1996: pp. 1–38). The 'British civil wars,' or 'War (or wars) of the three kingdoms,' had begun in Scotland after Charles had attempted in 1637 to impose a new prayer book on a reluctant Scottish people. The Bishops' wars, in which the Scots covenanters had emerged victorious over their English opponents, had forced Charles to turn to parliament in 1640 and made him increasingly dependent upon that institution. The outbreak of Irish Rebellion of 1641 had widened the rift between king and parliament, particularly as rumors spread of Charles's sympathy for the Catholic rebels. Neither side trusted the other to command an army to suppress the rebellion, and the raising of forces by both sides helped bring about civil war. Parliament eventually emerged victorious, but it is doubtful whether the war could have been won without the military support provided by the Scots Covenanters. In the 1650s Scotland and Ireland effectively came under English rule, and it was the English army in Ireland, under Monck, which began the process that led to the restoration of monarchy in England in 1660.

The new British history, as applied to the events of 1640–60, encouraged historians to abandon wholly anglocentric approaches to the study of mid-seventeenth-century English history, and, perhaps unintentionally, helped raise further questions about the very existence of an 'English Revolution' in 1640–60. Some scholars continued to insist on the revolutionary nature of events in those two decades, while falling back on more specific dates – 1640–41, 1640–42, 1648–49, 1653, or 1659 – to locate the moments when truly revolutionary changes took place. Other leading historians of the 1640s and 1650s expressed doubts over the validity of the term 'the English Revolution' to describe what had happened in these decades. For Blair Worden, the civil wars had "transforming effects, albeit inadvertent ones," but they should not really be seen as "a 'revolution' of the kind which, in France and Russia – and in the American War of Independence – would transform, and be intended to transform, perceptions about the nature of politics or of liberty" (Worden, 2009: p. 156). Austin Woolrych accepted that "rebellion is a totally inadequate term with which to describe what happened in the 1640s and 1650s," yet while he acknowledged that the events of these years could usefully be described as a period of revolution, he welcomed the fact that "the designation of them as 'the English Revolution,' so widespread a generation ago, is fading out of use" (Woolrych, 2002: pp. 1–3, 792–796).

Robert Brenner's wide-ranging study of commercial change and political conflict in the period 1550–1653 offered a new and ambitious attempt at a social interpretation of the English Revolution. Building on his earlier work on the rise of agrarian capitalism in England, Brenner accepted the limitations of traditional social interpretations and sought to demonstrate instead the decisive role of 'new' colonial merchants, many of them drawn to political and religious militancy, as a driving force for change. But even he

acknowledged that much of what had been achieved in 1640–60 was reversed after 1660, and that it was only with the successful outcome of the 1688 revolution that earlier gains were consolidated (Brenner, 1993). More troubling for those who still wish to claim that the English Revolution took place in 1640–60 has been the recent revival of research interest in the events of 1688–89. For Tim Harris, it is to "the later seventeenth century that we need to look in order to discover the revolution – in the modern sense of the word – that truly transformed the early modern British polity." The old order was firmly restored in 1660; it was only after 1688 that a radical, and lasting transformation was possible (Harris, 2005: pp. 32–38). Steve Pincus has called the revolution of 1688–89 "the first modern revolution." It wins out over 1640–60 because so many of the changes experienced in the earlier period proved ephemeral; many men and women became revolutionaries in the middle years of the seventeenth century, "but they did not achieve a revolution" (Pincus, 2009: pp. 474–482).

Where does this leave 'the English Revolution' of 1640–60? Lawrence Stone, who was in no doubt that a genuine revolution had taken place in these years, was prepared to admit as long ago as 1972 that the revolution's success in permanently changing the face of England was slight. Rather, what was most important about the revolution was its intellectual legacy. The trial and public execution of the king, the abolition of monarchy and of the established church, the toleration of a wide range of beliefs, and the rise of groups proclaiming ideas of liberty, equality, and fraternity all had a radically transformative effect. Ideas, once expressed, could never totally disappear from view. It was, Stone argued,

> this legacy of ideas which makes it reasonable to claim that the crisis in England in the seventeenth century is the first 'Great Revolution' in the history of the world, and therefore an event of fundamental importance in the evolution of Western civilization.
>
> Stone, 1972: pp. 146–147

Current research on the revolution would seem to bear out Stone's conclusions. Jonathan Scott has suggested that we misunderstand the revolution if we think of it primarily in terms of institutional or constitutional change. Rather, the English Revolution was about ideas: "English radicalism ... *was* the English Revolution" (Scott, 2000: pp. 33–34). The reaction to the religious policies of Charles I manifested itself in religious anti-formalism, and this could be seen to have been the driving force of English Revolution radicalism. Radicals such as the Gerrard Winstanley, Abiezer Coppe, Laurence Clarkson, and George Fox demonstrated a marked anti-formalism in their writings, which enabled their ideas to develop in wholly unexpected ways. In Winstanley's case it helped lead him to a rejection not only of all organized religion but also of private property and monetary exchange. Constitutional anti-formalism led to the discarding of old-established institutions and to the adoption of new and innovative constitutional models, which, in turn, lasted for only so long as they were seen to serve their purpose. Leveller radicalism, with its emphasis on fundamental and inalienable rights, was a product of the revolutionary decades, and it was in the 1650s, particularly in the person of James Harrington, that England made some of its most significant contributions to the history of republican thought. Harrington's *The Commonwealth of Oceana*, which was published in 1656, was to have an influence far beyond England and well beyond the seventeenth century. Royalist writers too may be said to have laid the foundations of modern conservatism in the revolutionary decades (Wootton, 1986: p. 9). In the religious sphere, the breakdown of the established church in the 1640s led to a proliferation of sects and beliefs. The church was restored after 1660, but the religious settlement that followed was an exclusive one, and many remained outside of it. The nonconformist tradition, which was to have such a profound influence over the intellectual life of the nation in the following two centuries, was thus another product of the mid-seventeenth century conflicts. Finally, as Christopher Hill remarked, the fate of Charles I provided a reminder to all future kings that they had a joint in their neck – perhaps James II would not have taken flight so swiftly in 1688 had he not remembered what had happened to his father. Hill may have been overoptimistic in seeing the English Revolution of 1640–60 as a successful bourgeois revolution, in which the crucial changes in commerce, state, and society had all occurred by 1660. Guizot and Marx were, it seems, more correct in recognizing that fundamental change was not concluded before 1688–89. Nevertheless, in the realm of ideas, the English Revolution of 1640–60 had a lasting impact, one that helped shape the course and outcome of the revolution of 1688 and influenced the American and French revolutions of the following century.

Enlightenment

Abstract

The epochal concept of modernity, Enlightenment, describes the style of thinking that predominated in the eighteenth century. It is difficult to periodize strictly. It started with the 'crisis of the European mind' in the last decades of the seventeenth century, reaching its maturity in the 1750s to the 1760s. The Enlightenment made a strong contribution to the crisis of the Old Regime, creating some premises of the French Revolution, up to Romanticism. Reason, experience, public opinion, and cosmopolitanism were considered operative tools. This article stresses the 'reinvention of the Enlightenment' against cultures menacing democracy and liberty. It is difficult today to consider the Enlightenment as a conceptual unity (as Cassirer did), as differences and varieties prevail in recent interpretations. In this, national contexts have played an important role and so have new perspectives: not only the history of ideas, but also gender studies and cultural history. In this way, a previous, unitary conception has been challenged by different Enlightenments: it can be 'conservative' (Pocock) or 'radical' (Jacob and Israel). Debates since 2000 have included those surrounding Israel and his Radical Enlightenment, the five volumes by J. Pocock and his Conservative Enlightenment and its compatibility with Empire, as well as themes such as religious universalism, human rights, and Pierre Bayle's challenge concerning virtuous atheism, of particular relevance to a society like ours, which can be seen to be without religion, with few civic ethics and even postsecular. The last challenge concerns the continuity or fracture between the Enlightenment and the French Revolution.

Definition and Meaning

Enlightenment is an epochal concept of modernity. It can be compared with others that preceded it such as Renaissance and Baroque, or followed like Romanticism, the latter mostly as its antithesis. The word Enlightenment is molded exactly on its German original, *die Aufklärung*, the first conceptual definition of which was due to Immanuel Kant; in 1784, he had tried to explain the meaning of the word to the readers of a Berlin journal. The first point to be borne in mind therefore is that the term was condensed with theoretical precision in a German area and that Enlightenment (second half of the nineteenth century) or *Illuminismo* (beginning of the twentieth century) were created as translations of the German term. But the concept of *Aufklärung* has had several metaphoric equivalents in European culture since the eighteenth century. The best known are linked to the term light, which in its turn is connected with reason: therefore Enlightenment was conceived from the very beginning as the Age of Enlightenment, emancipating reason, the time of humanity's coming-of-age. This is what Kant meant. Reason is a critical tool allowing humans to get rid of prejudice, to change the world, dominating nature through science. Enlightenment is conceived as a culture of conscious change, that is, of reforms, the secularization of a term that was originally in the singular and expressed a religious concept of modernity.

It does not mechanically coincide with rationalism, but it is one of its essential and critical moments. In fact, a rationalistic conception of the world precedes the Enlightenment and really belongs to the seventeenth century, as philosophers like Descartes and Spinoza could show. With them, reason is a system, whereas with the Enlightenment it becomes a method. Reason becoming method is an essential point of enlightened epistemology, which not only uses Locke's empiricism, but also Newton's celebrated motto, 'Hypotheses non fingo.'

Times, Spaces, and Routes

As for all complex epochal categories, it is not easy to imprison Enlightenment in a definite period in time or space. The fact that the concept originated in a German area does not necessarily mean that the center of Enlightenment is linked to that environment. From a historiographic point of view, at least three great European cultures claimed to have given origin and identity to the Enlightenment: France, England, and the German world. As far as France was concerned, the capital of Enlightenment (light) was Paris, in the name of the *philosophes* and of the *Encyclopédie*, which synthesized its essential knowledge. London could not only boast Locke's and Newton's contribution, or the precocity of the freethinkers, and later the great lesson of Scottish intellectuals, but also its own political system, already based on the separation of powers, and above all on the rapid evolution of public opinion, favored by a free press. The Germans in their turn claimed not only that they had first created the conceptual condensation of the term, but also that they had given (through Leibniz, Wolff, and Kant) Enlightenment a philosophy. Actually, these claims implicitly conceal all the ideological processes of the following age, which perceived cultural identities on a national basis, in antithesis to Enlightenment, thus denying a fundamental presupposition, cosmopolitanism.

If one wants to understand the Age of Enlightenment today, one has to not only put aside any simplification identifying center and peripheries, but accept its polycentric nature, which should be considered as a European and worldwide circulation of ideas, to which Kant attributed the choice of universal emancipation. This does not mean that one should ignore the diversities that have induced some scholars to imagine the existence of various kinds of Enlightenment. A polycentric interpretation probably helps better than others to save the unity and the diversities of Enlightenment at the same time.

 http://dx.doi.org/10.1016/B978-0-08-097086-8.62004-4

It is never easy to define the period of time enclosing an epochal concept. If one compares the cultural events of France, England, and Germany with those of other areas from the Mediterranean sea to the north of Europe, one can take the 1680s, indicated by Paul Hazard as the beginning of the 'crisis of European conscience,' as a starting point, provided one does not fix dates or individual events. They were the years of the revocation of the Edict of Nantes, of the querelle between the Ancients and the Moderns, of the appearance in European culture of Etrangers Symboles ('foreigners symbols'), like the Chinese Mandarin, archetype of virtuous atheists. In England, it was the period not only of intellectual maturity with Locke and Newton, but also of freethinkers like Anthony Collins and John Toland. Thomasius and Leibniz were the protagonists of the *Frühe Aufklärung*. In Holland, refugees like Pierre Bayle and Jean Leclerc elaborated the tools of a great critical culture. Only slightly later, the adventure of Giambattista Vico, Pietro Giannone, Alberto Radicati, di Passerano, and Ludovico Muratori had its beginning in Italy. As for the Iberian Peninsula, the *décalage* was greater.

The 1730s and 1740s can be considered years of transition, with the important exception of Voltaire's and Montesquieu's France, which inaugurated the Age of Enlightenment. In England, the radical culture of freethinking died out, whereas the Augustan season asserted itself through Samuel Johnson. In Italy, Radicati and Giannone succumbed to the success of the érudites and of the enlightened Catholics (from Scipione Maffei to Muratori). The latter's Spanish equivalent was Father Fejio.

The 1750s and 1760s are the season of Enlightenment at the height of its glory. The circulation of ideas linked together all the European centers. Not only Paris, London, Berlin, or the cities of the great cultural mediation like Amsterdam and Geneva, but also Madrid, Lisbon, Milan, Naples, St Petersburg, and Stockolm became involved in a close dialogue. These were the days of the *Encyclopédie*, of the *Contrat Social*, of Cesare Beccaria's *Dei Delitti e Delle Pene*. Learned periodicals became journals of opinion. The first great reforms were introduced in the fields of economy, legislation, politics, and morals. Pombal's Portugal opened a confrontation with the Jesuits in which all the Bourbon states would become involved and which would have an echo in the great European enlightened culture.

The network of freemasonry developed the political language of a civil society, deeply entwining itself with all the other tools of European intellectual sociality. Reforming projects were most fruitfully nourished by Utopian ideals. Enlightened absolutism made its tentative appearance in Austria, Russia, Prussia, Tuscany, Denmark, and Sweden. If sovereigns were drawing near to the philosopher's projects, there was also a fruitful exchange between enlightened culture and the governmental experience of a new generation of officials.

The 1770s and 1780s, when little by little the generation of the great representatives of Enlightenment (Voltaire, Rousseau, Diderot, D'Alembert, and d'Holbach) disappeared, witnessed an Atlantic event – the American Revolution, which gave Europe firsthand ideological material on questions not yet approached, such as the self-determination of peoples, parliamentary representation, and federative connection within a republican model: liberty, democracy, and civil ethics as a shared and written constitutional project. Europe's boundaries widened with Russia entering the Mediterranean, and the inevitable modifications of the eastern balance. Historians like Edward Gibbon and law reformers like Gactano Filangieri took note of it. The models of reason changed. Freemasonry itself, which Lessing thought the ideal tool to diffuse Enlightenment, experienced a deep restlessness and the clash between operative rationality and a taste for the occult and mysticism. Raynal, who had enjoyed Diderot's collaboration, attacked the European colonial models, denouncing both their violence against other civilizations as well as slavery and their inclination toward despotism; he went so far as to assert that the torch of freedom would be carried to Europe by a black Spartacus.

It is not easy to find an *ad quem* term. The beginning of the French Revolution, a starting point of an epochal crisis, is plausible beyond a logic privileging the French course. Some frontier areas were soon involved in the revolutionary turmoil. The process seemed to take longer in Germany, England, Spain, Portugal, and Italy, not to mention in Eastern Europe. The French Revolution and war put a stop to the politics of enlightened absolutism. The crisis of enlightened culture and its transformation into something different (from Jacobinism to counterrevolutionary resistance) lasted through most of the 1790s. As for England – which experienced the first unsettling industrial revolution – it carried out an uncompromising war not only against the French Revolution, but against the Napoleonic Empire as well, yet this did not modify its constitutional evolution, nor did it alter substantially the role of public opinion. This is true also with regard to the United States, which would later appear to an observer like Alexis de Tocqueville (*De la démocratie en Amérique*, 1835) as the most mature and complete project of the Enlightenment, from which the Europe of *Restauration* would have to learn freedom and democracy anew.

Operative Tools and Fields

An analysis of the categories of space and time connected with the concept of the Enlightenment implicitly shows its operative tools (reason, experience, criticism, scientific models, reforms, Utopian tensions, and theories of progress and of public and private happiness). Each of these terms not only has its own internal dynamics, but also tends to adapt to highly differentiated realities. Enlightenment today does not appear so much as a clear unitarian philosophy, according to its reconstruction by Ernest Cassirer (1932), but as a process of general emancipation that moves hypothesis, possibilities, and strategies that might appear different and antithetical at first sight. This is clear from a brief analysis of its main fields of influence: religion, ethics, politics, economy, history, social transformation, and cultural change.

As regards religion, in the long term, secularization had its roots in the first period of modernity (humanism, renaissance, reformation, and libertinism). Criticism of revealed religions was an important element of English freethinking in the early eighteenth century, with repercussions not only in Holland, but also in France and Italy. Materialism, pantheism (the term was coined by Toland in 1704), and the negation of the immortality of the soul involved both the protestant and the catholic world, as the religious adventures, destined to be

defeated, of Jean Meslier, Giannone, and Radicati di Passerano demonstrate. The progressive reduction of magical, miraculous, and prophetic forecast practices were generalized as the refusal of superstition. With fruits of the application of critical models linked with philosophy and science, they created various intersections between faith and reason, from reasonable Christianity to enlightened Catholicism, to natural theology, to deism. Tolerance, which is not only the cohabitation of different religious confessions on the same territory, but also the possibility (enunciated by Pierre Bayle) of individual conscience to err, without any church arrogating to itself the power of constraint, was a good ground for testing important conquests. In the wake of a great juridical tradition, Voltaire would take this battle into the very core of the Enlightenment, elaborating for European public opinion the theoretical premises for the choices of Prussian, Austrian, and Tuscan enlightened absolutism.

D'Holbach's *coterie*, which represents the most radical experience of the French Enlightenment from a religious point of view (with two phases: the first an anti-Christian offensive; the second the elaboration of a social model where ethics and politics were separated from religion) is only one of the components, although the most aggressive and sensational, of the French and European Enlightenment. It is all too easy to underline its elitist nature, limited to a small group speculating with the complicity of European publishers interested in creating a flourishing market of clandestine books. One should not underestimate this aspect, after a scholar like Robert Darnton explained the relation between publishing and sedition, between forbidden books and a crisis of political, ethical, and religious social structures.

The most lasting result of the Enlightenment in this field was the widespread consciousness not only among laymen but among priests as well, including enlightened Catholics, that religious choice mainly belonged to the private sphere. In this sense, the most mature enlightened project had accepted and adapted for a larger civil society the rights of conscience proposed by Bayle at the time of the 'crisis of European conscience.'

Emancipation, Reform, and Utopia

In its most essential and creative moments, each innovative choice of the Enlightenment was preceded by an ethical reflection that cannot be mechanically reduced to an individual reckoning of pleasures and sorrows. The utilitarian moral itself had imagined with Bernard de Mandeville that private vice could become public virtue, but in the middle of the eighteenth century, it was perceived more as a tension to ensure the maximum happiness to the largest possible number of people. From this point of view, the analysis of Montesquieu's works, of the 'économists,' of Pietro Verri, Beccaria, and Gaetano Filangieri, is important because of the strong relation they establish with a new ethical project. The Scottish Enlightenment also started from morals to discover economy and sociology. In fact, one of the concepts most charged with future, that of 'civil religion' theorized by Rousseau in his *Contrat social*, was based on a profound understanding of natural law (above all through Jean Barbeyrac), which had tried to set the field of man's rights and duties free from the traditional links of Patristics and Scholasticism.

Rousseau and Mably had transformed this inheritance and founded a new system of the rights and duties of the citizen. The state took upon itself new tasks in the fields of instruction, cultural control, and assistance, thus widening its public dimension and secular action; as a consequence, religious choice tended to become a private question, involving the intimate and inviolable sphere. The most significant lesson of the Enlightenment was not so much a lay morality opposed to the religious one, as the possible dialogue on the field of citizenship between different kinds of ethics: a difficult project, continuously interrupted, which modernity has to tackle all the time.

Also, from the point of view of political models, the Enlightenment does not show a unified front, but a series of possible choices, from enlightened absolutism to the return of a republican culture, to the bureaucratic centralization of the 'well-ordered police state,' to constitutionalism, to debates on representation, to projects of direct democracy. Each of these terms in fact can be used to define very different experiences, unless there is the intervention of a contextual historical event. There is a sharp distinction, for example, between the forced modernization of Peter the Great, which is an example of reformism to the point that it attracted Voltaire's attention, and the strategies of 'enlightened' princes like Frederick II, Joseph II, Peter Leopold, and even Catherine the Great.

In the same way, with regard to republican thought, one should not confuse the patrician models of the republics, which survived the success of absolute power (Holland, Venice, and Genoa), or the mannered republicanism one learnt by reading the classics, with the new republican tensions that arose as a consequence of the claims for freedom of the Poles, the Corsicans, the Genevans, and above all the American colonies. But enlightened absolutism itself attracts or repels enlightened thinkers because of two equal possibilities. The first is the use of centralization in order to carry our reforming politics, where the accent was not so much on strength, however, necessary to win resistance, as on the involvement in the project of new fields: law, politics, economy, religion, and culture, together with the elimination of particularisms and unjust social relations. This implied the other necessity, that of transforming the model into constitutional forms. The process of emancipation, and of adaptation to the complexities of the real world one wants to change, Enlightenment moves between the two poles analyzed by Franco Venturi (1971): Utopia and reform, closely entwined. These two tensions vivify each other. But the course of the Enlightenment revolves round another two essential terms: freedom and democracy. The first term above all was the main object of Montesquieu's *L'esprit des lois* (1748). It is not possible here to go beyond a schematization recognizing virtue as the essential value of republics, as distinguished from honor, the real ethical and social cement of monarchies. Montesquieu did not choose among the different political forms. He only discarded Asian despotism and was very diffident against absolutism, which he wanted to temper not only by separating the three powers, or through the binding strength of the laws, but also through the concrete presence of intermediate bodies, including the nobility.

The other term of reference for the political theory of the Enlightenment is Rousseau. He opposed to eighteenth-century cosmopolitism the love for one's own country, which requires the practice of direct democracy. Rousseau's democracy is right for a small republican country. It does not admit representatives. Between majority and minority, only the former represents the general will, because sovereignty derived from the social pact cannot be divided. The Genevan's challenge was even more complex: he questioned a developmental model of civilization based not only on the progress of art and science, but also on the basis of social inequality. Democracy was the courage to modify ownership, justice, and instruction. A large part of later political thought is linked to a comparison between Montesquieu and Rousseau, to establish a connection between freedom and democracy, the aspiration to absorb the Genevan's Utopian drive and transform it into a spirit of reform. An exemplary text is *Dei delitti e delle pene*, which questions the right to punish in an unjust society because it is unequal.

Various other experiences belong to Enlightened politics: cameralism, an administrative model mainly used by Prussian and Austrian officials; the physiocratic theory of legal despotism, in which a monarchic power guarantees certain natural laws, among which is ownership. From the above considerations, it appears that the question of enlightened politics is narrowly linked with the question of law, which becomes the 'science of legislation.' The weaker field was feminine political and cultural identity. For this question, one would have to wait for Mary Wollstonecraft and her work on women's rights.

Economy became a science during the eighteenth century, evolving from late-mercantilist models. The physiocratic project established the essential points of the productive cycle based on agriculture and on free corn trade. If agriculture was the only wealth-producing sector, while transformation and circulation were the task of industry and commerce, taxation had to become progressive with respect to land, whose ownership was one of the fundamental natural rights. Adam Smith extended liberalism to sectors such as industry and commerce, which were not considered subsidiary, but highly productive. In this way, the first strong perception of an industrial revolution under way in England became a theory. During the last decades of the century, there was a return to protectionism.

What happened with the economy could well be verified with other sciences, not only social and natural, but human as well. The Scottish school created the premise for sociology, by studying social stratification or the concept of civil society. Economy itself, by defining a stages theory based on production, laid down the basis of anthropology. Consolidated disciplines like physics were renovated, as well as chemistry, geology, agronomy, and geography itself. Linneus and Buffon had reclassified nature, thus rendering it an open book. Natural history had given a common language to the natural and biological sciences.

As for history, one can only register a change in some fundamental paradigms: the loss of the superiority of sacred history, the transformation of ecclesiastical history into the history of religions, the emergence of the history of civilization within new models of universal history, the flourishing of civil history as institutional history, and the first appearance of the history of science.

Circulation and Practices: the Growth in Literacy

If one examines this process from the point of view of cultural history and of the general transformation of intellectual models, European and even the worldwide circulation of ideas can be measured through parameters that are apparently external to intellectual history, but not unimportant. The author refers first of all to the international book market, and to the creation of an incredibly large number of tools, thanks to which the consultation of books was made possible, from public and private libraries to bibliographies, catalogues, abstracts, and reviews. Books and newspapers gained an almost universal circulation. In Europe and America, there was an increase in literacy. The world of potential readers expanded not only thanks to the advent of the middle classes but because the distance between male and female instruction tends to diminish in urban spaces. Somebody called this the revolution of middle class readers. Even reading habits changed; there was a greater tendency for undirected reading, not linked to learned professions but to the consumption of leisure time. The demands of the new readers also brought about a change in genres. The novel had an incredible development, offering as it does to all classes means for education, identification, and escapism. Among the forbidden books of the second half of the eighteenth century, the *philosophique* and *pornographique* genres often followed the same semiclandestine circuits, thus contributing to the modification of the cultural and ethical general models of society. Music and theater as well were often fields for ideological formation and dispute. Journalism followed in the tracks of this expansion of the book market, and from the objectivity of abstracts, which are made for a public of learned people, moved to the subjectivity of journals, the concision of reports. Journals of opinion were essential for the formation of this new international public sphere, which discovered languages, interlocuters, and spaces. To this sphere belong the salons, public, and private spaces at the same time. Intellectual sociality took a number of forms, from the old and new academies, to clubs, to cafés, down to the taverns where conversation and gossip were a way for disseminating news. The Enlightenment–Academies relation is supported by a rich bibliography, starting with Reinhard Koselleck's (1959) work, which laid down the basis for a more through analysis of the links between Freemasonry and Enlightenment. The former is now considered the privileged center for the formation of the political language on which the assemblary model of the French Revolution would be created.

Many centers of intellectual communication reverse the prevailing male image one received when analyzing the concept from the point of view of intellectual history. Women were present in the famous French salons, where they have some personal control over an ephemeral though socially important genre like conversation. They started being accepted in some lodges and academies, their role thus changing from that of consumers of books and newspapers (also of a literature for women, produced by men) to that of writers. First, they occupied the space of women's literature, then they took an

active part in the journalistic debate. The inclusion of women in the public sphere does not alter the fact that their role was still subordinate. Women's writing often tends to self-identification, but it remains unfinished, secret. And this corresponds to a social model that is prevalent in the male-dominated Enlightenment. Rousseau, who had put the question of the public education of citizens, had kept women separate; Filangieri himself had followed suit. This explains the novelty of Wollstonecraft's denunciation. In fact, the public sphere created by the High Enlightenment seemed to be threatened by new classes joining the world of writing and communication, forming an international Grub Street and living on collaborations and translations. The creation of a more aggressive political language, and of the use of reason both as prophecy and announcement of the crisis, broke the balance of the previous generations, which had reached the highest levels of intellectual communication in the academies, in the teaching and in the publishing world. In this phase, women seemed to live less apart. The fact remains that on this question Enlightenment as emancipation was a partial project delegated to the future, because it had not fully accepted the other half of its universe.

Building an Epocal Concept

Finally, it should be said that the French Revolution, while celebrating the Enlightenment as its parent, strongly contributed to its interruption first of all because what had survived as *idéologie* had to adapt to the heavy Napoleonic tutelage and stabilization, and second because the behavior and the propaganda of Napoleonic France were experienced by other European cultures as a violence that forced them to find anew their national, religious, and identifying roots. This explains why part of Romanticism set itself up as an antithetic culture to the Enlightenment that was considered responsible for the political conditions in Europe. Friedrich Meinecke spotted the opposition between cosmopolitism and the national state (1908). While new problems required new kinds of culture, certain fundamental values, after being driven underground during the *Restauration*, after the Napoleonic age, sprang up again in all the moments of opening to freedom and democracy, which are scattered in the history of Europe. In French history, the ideological elaboration of the Third Republic renewed the strong link between Revolution and Enlightenment again, the latter being dragged by the former.

The twentieth century, however, really needed to reflect on the Enlightenment again, having a critical period troubled by nationalistic, fascist, and totalitarian cultures that threatened liberty, democracy, and equality. These threats were answered by Cassirer's (1932), Becker's (1932), Hazard's (1935, 1946) and many other projects. From these roots, there originated an important historiography (Venturi (1971), Gay (1967), Koselleck (1959), Pocock, Darnton, Jacob (1980), Roche, and many others) that to this day finds an echo in the International Society for Eighteenth Century Studies and in the dense network of National Societies. Margaret Candee Jacob has written about a 'Radical Enlightment,' which was masonic, pantheist, and republican. John Pocock (1999), more recently, has located in the English world a 'Conservative Enlightenment,' while Jonathan Israel (2001) widens the chronological terms of a European 'Radical Enlightenment' and 'its making of modernity,' starting from 1650.

There are also many publications on the limitations, deficiencies, and responsibilities of Enlightenment in the evils of modernity, to begin with T.W. Adorno and M. Horkheimer (1947). But in the light of the dramatic problems of our times, many evoke the necessity of a further Enlightenment, of a future of Enlightenment that will resume the interrupted project. One can well imagine that it will inevitably be a new one, because the past can give inspiration, but not necessarily return. It is true, however, that we must find our own answers to emancipation, freedom, and Utopia for the world otherwise risks being an icy globality without universalism.

Recent Discussions and New Themes about Enlightenment (2002–12)

Israel's work on the Radical Enlightenment and its prosecution has been the occasion for an interesting debate, which can be summarized by describing the conclusions of a meeting organized in France (Lyon) in 2004, an occasion to verify the terms implied, starting from the retrodating of the Enlightenment to the time of Spinoza: Israel considers spinozism the main root of the radical project. The organizers of the meeting agreed that Israel's work had reopened the discussion about the Enlightenment, but he faced serious criticism, not only about a solution that implies a key that is too restricted, but also one that is primarily resolved in terms of intellectual history. Also deemed to be of importance was his decision to produce a transnational history. The problems surrounding the chosen key are confirmed by the second volume, *Enlightenment Contested* (2006), which strangely enough returns at the first half of the eighteenth century. Also, the recent book on the revolution of the mind reveals that the connection between the Radical Enlightenment and the French Revolution, strongly defended in the previous volumes, is less linear than previously suggested. With his last volume, *Democratic Enlightenment* (2011), Israel not only has completed his huge opus concerning the Enlightenment and its roots, analyzing the temporal and spatial period between 1750 and 1790, but also answers his critics starting with Antoine Lilti, now leader of the 'Annales,' and an important scholar of the world of the Parisian salons in the eighteenth century, critically connected with social and cultural history. On the basis of his reading of the first two volumes, Lilti accused Israel of practicing only an old intellectual history. It is easy to perceive in the pages of the 'Annales' (3, 2009) a defense of a model of history, connected with great scholars such as Robert Darton, Roger Chartier, Daniel Roche, and others, but in some ways a sort of flagship of French historiography. Confirming his previous choice, Israel has good reasons not only to demonstrate that cultural and social history have not produced a general and transnational reconstruction of the Enlightenment as a worldwide 'revolution of the mind,' but also that his history is not the old intellectual history, focused solely on ideas. He considers also social processes of transmission, transformation, conflicts, and secret sects such as masons, all connected with a society not of the happy few, or the great intellectuals, but

rather collectivities of men and women. He also confirms his agreement with John Robertson about the unity of the Enlightenment, and its distance from the huge national project by Pocock, which separates Gibbon not only from the French, but also from the transnational Enlightenment. It is true that he insists on the keyword philosophy, but it incorporates religion, criticism, philology, as well as politics, science, and law. It is a fundamental tool of transformation, but only if it involves collective and conflicting social energies. Israel is open in his polemics against a model of history that reduces all to interpretation, literary artifact, or communication. But the best answers are on the terrain of the research. The first part on earthquakes involves not only Lisbon, but also South America and is a way to verify the differences between science and superstition, Nature and Providence, materialism and deism, philosophers and antiphilosophers, as social groups with their tools of propaganda. The challenge involves also Jean Jacques Rousseau and his growing distance from the *philosophes* and the 'Encyclopédie.' The chapters concerning the main tool of the French *philosophes* not only are clear and rich, but also incorporate the findings of Darnton. Less convincing and perhaps too simplified is what he has to say about Rousseau, considered more for his deism and antimaterialism than for his *Contrat social*. In the reconstruction of a transnational and complete image of the Enlightenment the second part, 'Rationalising the Ancien Regime,' is impressive, revealing a global vision, which connects the different European cultures, and political forms. Action and reaction, projects and resistances are clearly analyzed for all European countries. The third part, 'Europe and the Remaking of the World,' considers America, not only the North and the crucial event of the American Revolution, but also South America as well as Spain and Portugal India, China, Japan, and their relationships with different European cultures. This section reveals Israel to be perhaps the best pupil of the great John Eliott. He also accepts from Sankar Muthu that Enlightenment is against Empire. The fourth part is dedicated to the return of Spinoza: he defines in one of the central chapters *Pantheismusstrei*, involving France, but above all Germany where Lessing opened a Radical or Democratic Enlightenment, while Kant fought against Israel's hero, Spinoza, inventing an idealistic philosophy. The fifth part, dedicated to the French Revolution, appears a correct reconstruction of the glorious moment in which the Third Estate celebrated its triumph against Monarchy, Aristocracy, and the Church. It is easy to be persuaded by this part of the benefits of a Revolution, which erased the *Ancien Régime*, and invented Human Rights. The author is persuaded that a strong contribution to this field was offered by *philosophes* such as Rousseau and later Filangieri, in relation to the American Revolution. Also, Kant was an admirer of this phase of the French Revolution, but it is also true that Hegel, considering the Terror and the Napoleonic European authoritarian order, held the Enlightenment responsible. This book merits to be read with a great respect for its huge intellectual courage, and its capacity to answer many objections of his opponents. Respecting the project involves considering all three volumes. It would appear that for a long time this will be the main reference in the field. In this sense, the author thinks that *the lector in fabula* now has certainly the duty to correct single judgments, but doing that, must respect one of the intellectual adventures that can be compared only with Paul Hazard's opening a European Resistance, by Franco Venturi's continuation of the same Resistance, or now also by John Pocock.

Another great project is almost concluded. The author speaks about the five volumes by John Pocock, in which he utilizes the great historian Edward Gibbon not only to confront him with the proposals of the French Enlightenment, stressing the differences, but also to reconstruct the way in which the eighteenth century's English world debated great themes such as Empire and colonialism. The history of the past is here a means of considering the future. Pocock confirms the compatibility between a Moderate or Conservative Enlightenment and the imperial vocation of Great Britain, connected with the Union of 1707. He reads Roman history as a metaphor for the English colonial and imperial choice. The problem has been largely discussed not only in England and in the United States, but also in other countries. Sankar Muthu has demonstrated that Enlightenment and Empire were opposed (2003). The Scottish Enlightenment and its connection with the Union have been analyzed not only by J. Robertson, but also by G. Abbattista on Empire, D. Francesconi, considering 'the age of history' (2003), and S. Sebastiani, speaking about 'the limits of progress' (2008).

A new problem and field of research has emerged, as a creation and inheritance of the Enlightenment, around human rights. The terms, not coincidentally, emerged with Rousseau and Voltaire in the 1960s, becoming central in the 1970s and above all in the 1980s. The invention of human rights became central with the American Revolution and also in the Declaration of the Rights of the Man and the Citizen at the beginning of the French Revolution, connecting the birth of the United States with Europe. Not only did Diderot invoke liberty by a black Spartacus, but he also has a recent critical edition of Gaetano Filangieri's *Scienza della legislazione*. The study of its translations has confirmed the presence of human rights, republicanism, and constitutionalism in the 1980s in Europe. The Italian contribution has been emphasized by Ferrone in his research on Filangieri (2003), recently translated into French. Now he is writing about human rights, a problem announced in a chapter of his *Lezioni illuministiche* (2010). An attempt at studying human rights in the eighteenth century has been realized by L. Hunt (2007). She had formerly opened the question in 1996 with regard to the French Revolution. Her new fascinating enquiry explores the essential role of the novel to form general ideas of empathy, sympathy, identification, and knowledge of the Other, inventing a deep need for equality and preparing a diffused persuasion in the West that men, women, and also blacks had the same natural rights. If the function of the novel is well analyzed, it is possible to remark that the research about law, politics, and philosophy is instead reduced. Hunt explains the long self-evidence of the concepts connected with human rights and also the limits of their concrete application. If Rousseau (1762) and Voltaire (1763) individuated the concept and the words, the first attempt to define them emerged in 1776, to be deepened in 1789. Less explored here is the attempt at translating the seventeenth-century tradition of natural law realized for the future by Jean Barbeyrac, which echoed across Europe. Cesare Beccarla is quoted only through Morellet's translation. But the roots of human rights connected Vico, Genovesi, Filangieri, Pagano in Naples, and also Peter Leopold in Tuscany, as implicitly emerged in Furio

Diaz and Venturi's researches and now explicitly in Ferrone and Trampus. On empathy and the novel in the eighteenth century it is now also necessary to read R. Loretelli (2010).

Human rights have been connected with republicanism, as the mainstream (M. Viroli and others), but recent international research has verified that concepts such as liberty, public happiness, the common good, equal rights, patriotism, and also constitutionalism were present in *Monarchisms* (2007). England was not the only nation that evolved in this sense, but also Tuscany and the Hapsburg Empire, where Leopold II corrected Joseph II's centralism, a process interrupted by the French Revolution.

Another problem anticipated by researchers on the history of historiography, the history of philosophy and comparative studies again in Italy (G. Ricuperati, S. Berti, R. Minuti, and L. Simonutti) has been deepened recently by an international team of historians: L. Hunt, M.C. Jacob, and W.W. Mijnhardt, in two recent books exploring a huge work that was born in Amsterdam between 1723 and 1733 in seven folio volumes, involving J.F. Bernard, the editor, and an anonymous writer of the texts and B. Picart, one of the best engravers of his time, *Cérémonies et coutumes religieuses de tous les peuples du monde*. The researchers, who are connected with prestigious American and Dutch universities and international foundations such as the Getty Museum, have stressed the role of this creative compilation, described as *The Book That Changed Europe* (2010) and the first attempt to construct an innovative history of religions, which, through the confrontation of rituals, did not distinguish between monotheisms and polytheisms, opening in this field a true religious universalism in a preanthropological sense. The second book on Picart similarly involves a lot of problems of research and interdisciplinary competences (2010). The two works document not only the indifference of the anthropologists toward this creative and precocious approach, but also the ideological change presented in the later editions. If the Parisian edition by Antoine Banier and Jean Baptiste Le Mascrier was an attempt at orienting the project in a Catholic direction, the French and English editions of the nineteenth century were dominated by regressive and dangerous ideas of the superiority of the West and of Christian (Protestant) monotheism.

Also, the debate about the great challenge suggested by Pierre Bayle, in dialogue with Hobbes and Spinoza, about the 'virtuous atheist' and more generally about a society with civic virtue but without religion, has been reopened with regard to two different, even opposite, perspectives: the first is connected with the Radical Enlightenment and the roots of a cosmopolitan modernity; the second, which emerged in recent years as a result of a diffused consciousness of a strong return of institutional religions, considers our society as postsecular. The defeat of secularization is strongly connected with the pretension of Catholicism to have invented human rights, subtracting them aggressively from the secular Enlightenment. The same happened in other religions and sects that were also against science.

The last object of discussion is the connection between the French Revolution and the Enlightenment. If Israel, in his first two books (2001 and 2006), confirms a deep continuity between them, as the necessary root of our secular present and future, his recent book *A Revolution of the Mind* (2010) seems to like neither the Terror and Robespierre, or his presumed source of inspiration, Rousseau, holding them responsible for totalitarian democracy, and reading the general will, as J. Talmon did, as the main root of future evils. How these arguments can be coherent with continuity is a problem that is not resolved here. For a different analysis, one can cite Ferrone and his *Lezioni illuministiche* (2010), who openly challenges this connection, which was invented in a conservative and conditioning sense by Hegel, and united in the same condemnation Revolution and Enlightenment, without true historical evidence. The author has posed the same perspective in a meeting about the Enlightenment and the French Revolution in Italian debates (Vizille, 2007) the fruits of which were edited in 2010 by G. Bertrand and E. Neppi. Also, B. Baczko in his recent book about the politics of the French Revolution (2008) stresses the difficulty in finding an exit from the Revolution, confronting Washington and Bonaparte. The Napoleonic imperial adventure sounds very different from the correct choice of the American Hero and his renunciation. The Empire was a dramatic way to depart from the Revolution, paid for in Europe with tragic wars, and with a reaction constraining the conquests of the Enlightenment to an underground survival, conditioning *Restauration*, Romantism, and the Age of nations to be without cosmopolitanism, with a regression of liberty and human rights, dreamed for by all Enlightened philosophers as Utopia and reform.

Abstract

This article examines the relationship between the Enlightenment and the modern social sciences. It details the different national traditions of 'Enlightenment' and how these have affected the trajectory of the social sciences. It explores both the ways in which the social sciences have sought to carry out an 'Enlightenment project' and the doubts that have been raised about that project along the way.

The modern social sciences are children of the Enlightenment. The signature statement heralding that movement in European intellectual history was Immanuel Kant's famous dictum (1959b: 85–87), "*Sapere aude*! (Dare to know!) Have courage to use your own reason! – that is the motto of enlightenment." The use of one's own reason was to be contrasted, of course, with that dispensed by others, perhaps especially by the hierarchically organized and doctrinally authoritarian Catholic Church. Hence the Enlightenment was in certain respects a continuation of the Protestant Reformation's insistence on the more egalitarian 'priesthood of all believers' and on the ability of each individual to find his or her own path to god. People should use their own reason *publicly*, according to Kant, and all that was required for the public use of reason was political *freedom*. The idea of Enlightenment was thus bound up from its origins with an emancipatory political outlook that has generally continued to accompany it ever since. The anticlerical character of the Enlightenment was perhaps most apparent in the French case, where the Catholic Church comprised part of the 'old regime' and was part and parcel of the unfreedom that Kant saw as the chief barrier to Enlightenment. Not surprisingly, then, Kant was a strong supporter of the French Revolution. His stress on the difficulty of achieving truly moral action – reflected in his distinction between the 'is' and the 'ought' – would resonate throughout much subsequent social science thought.

The establishment of social 'science' as an endeavor separate from the wisdom of the churches would mean that it would be forced to distance itself from theology, philosophy, and other modes of knowing that lacked a 'scientific' foundation. That scientific foundation would be derived above all from the insistence on the this-worldly, empirical character of the social sciences. Hence Weber would later say (1949: 72) that social science is an "empirical science of concrete reality" (*Wirklichkeitswissenschaft*) and that definition has very much shaped the nature of the modern social scientific disciplines, even if these fields may in fact be profoundly different from the natural sciences. The need to distance it from religious modes of thought has driven the self-understanding of the social sciences as 'objective' and 'disinterested,' leading to a widespread divorce between *knowing about* the world and *doing something in* the world. The link between contemplation and action that had animated classical Greek thought was severed in the process. There is something ironic in this, given that some of the founding lights of the social science disciplines, such as Tocqueville, Marx, Weber, and Durkheim, were very much involved in the politics of their day, some of them holding high public office (Tocqueville was briefly foreign minister of France). The divorce between knowledge and action would later be intensified by the massive expansion of higher education from the 1960s onward, as a result of which academics came to constitute an audience for each other and were no longer required to write for broader 'lay' audiences. The extent of the segregation of thought and action, and of the 'is' from the 'ought,' has varied, however, in the different national traditions of the social sciences that emerged from the eighteenth- and nineteenth-century background. As compared to European and other variants of the social sciences, American social science has been seen as distinctively "modeled on the natural rather than the historical sciences and imbedded in the classical ideology of liberal individualism" (Ross, 1991: xiii). Indeed, the nature of the American social sciences is arguably another aspect of 'American exceptionalism' (see Lipset, 1996).

In addition to strengthening the role of human reason in public life generally, the Enlightenment 'project' had a good deal to do with finding ways to pacify human life and to overcome the scourge of war. Kant himself, of course, articulated a design for 'Perpetual Peace,' in which he proposed an idea for a sort of 'league of nations' that anticipated later developments along these lines. He also suggested that countries' predisposition toward violence beyond their borders was a function of their internal structure, and that republics, in particular, tend not to go to war. Kant thus laid the groundwork for the theory of the so-called 'democratic peace,' which holds that democracies do not go to war with one another. The theory generated considerable research and controversy in the 1990s and after. Kant also drew on a body of thought articulating the theory of '*doux commerce*' – the idea of the civilizing function of commercial activity. One version of the thesis, which was advanced by Montesquieu, Hume, and others, came from the American radical Thomas Paine. In his 1792 tract *The Rights of Man*, Paine wrote (1992: 172) that "commerce … is a pacific system operating to cordialize mankind, by rendering nations, as well as individuals, useful to each other. If commerce were permitted to act to the universal extent it is capable, it would extirpate the system of war…." The idea of commerce as a system for regulating the passions of human beings would prove a central theme in the Enlightenment-era thinking about economics, war, and modern society (see Hirschman, 1977).

The Scottish moralists such as Adam Smith, Adam Ferguson, and others were preoccupied with related themes, examining the conditions under which republican government and civic humanism could exist under conditions of an advancing division of labor. Smith, perhaps most frequently associated with his 1776 treatise *The Wealth of Nations*, came to be regarded chiefly as a thinker concerned with economic activities, but – writing before the separation of social science and moral philosophy had been completed – Smith asked about the causes and consequences of those activities. "It is not from the benevolence of the butcher, the brewer, or the baker that we expect our dinner," Smith wrote (1985: 119), "but from their regard to their own interest." Along with man's supposedly innate inclination to 'truck and barter,' Smith developed a rational model of economic motivation that would dominate the social sciences – whether as touchstone or as bête noire – thereafter. Meanwhile, Ferguson was concerned with the requirements of citizenship and the promotion of civic virtue, among other things with regard to the degree to which citizens should be involved in defending the state of whose acts they would be the authors. In his *Essay on the History of Civil Society*, Ferguson advances a conception of the citizen-soldier that would, in its turn, resonate through later social scientific thinking about the relationship between citizens and military institutions. The concerns of Smith and Ferguson would resurface over and over again in subsequent writing about modern society, economics, and politics.

Soon thereafter, in the aftermath of the revolutionary *levée en masse* and the Napoleonic wars, the German officer Carl von Clausewitz would endeavor to think systematically about the place of war in modern societies in which ordinary people were increasingly included in political decision-making. Clausewitz's dictum (1984: 87) that "war is … a continuation of political intercourse … with other means" was intended to reflect the nature of war in an age in which citizen armies were becoming the order of the day. Gradually, however, as the social science disciplines developed, sociology and political science went their separate ways, and political science – the study of 'high politics' – more or less exclusively held onto the portfolio of war and international conflict. Meanwhile, sociology – the study of 'low politics' – largely abandoned the study of war, and tended to operate as if Enlightenment dreams of ending war had been realized and as if war were not an endemic aspect of modern society (see Joas and Knöbl, 2013).

From a more systematic perspective, however, the origins of the modern social sciences are often traced back to the French thinker Auguste Comte, who sought to create a 'positive' science emphasizing the observation of concrete phenomena (see Lenzer, 1975). Imbued with the postrevolutionary aims of order and progress, Comte sought to understand what *is* in order to understand what *would be* – in other words, to predict the future and make of it the orderly unfolding of human progress. The emphasis on prediction and on general laws of social development would come to play a pervasive role in social scientific thinking far into the twentieth century. Comte developed a scheme for understanding human history, according to which there were three stages of human development – the theological, the metaphysical, and the positive or scientific. Comte thus introduced a scheme in which positive or scientific thought was sharply contrasted with that of religion. The legacy of the French Revolution and its anticlericalism is straightforwardly apparent. Comte's contemporary Alexis de Tocqueville did not share the harsh dismissal of religion that pervaded the Revolution, and indeed regarded religion as a mode of thinking that was never likely to die out entirely. 'Religion,' Tocqueville wrote in an 1857 letter to Sophie Swetchine, "is only a particular kind of hope, and it is also as natural to the human heart as hope itself" (quoted in Brogan, 2006: 53). Still, the connection between the Enlightenment, the social sciences, and what would later come to be known as the 'secularization thesis' – the idea that religiosity would decline as modernity advanced – was growing stronger.

The thesis could not have acquired its power from Tocqueville's analysis of the varying place of religion in the French Revolution and in the United States, however, as he strove to point out that religion played a very different role in the two contexts. As an element of the 'old regime' in France, according to Tocqueville (1998), the revolutionaries who wanted to dispense with the French monarchy were ill-disposed toward the Church not because they were antireligious but because they were opposed to the regime of which the Church was a part. In the United States, by contrast, religion and freedom marched hand-in-hand, the one reinforcing the other. The result, according to Tocqueville (2000), was that religion flourished in the United States – despite its constitutionally mandated disestablishment – whereas it withered in France due to its association with a power rendered illegitimate by the advance of democratic ideas and forces. As his relatively sympathetic comments on religion may suggest, Tocqueville was not a great admirer of the Enlightenment, which he regarded as the underlying source of the "abstract theories of government" (1998: 197) that led to the Revolution and to the extremes of the terror. Notwithstanding a guarded sympathy for 'democracy,' Tocqueville tended to believe that local people knew better than central rulers what was best for themselves, and that the abstractions underlying the French Revolution led to an unfortunate fate for postrevolutionary France.

The connection between Enlightenment-inspired views of religion and the social sciences would intensify in the work of Emile Durkheim and Max Weber. Durkheim distinguished sharply between religion and magic in terms of their capacity for generating institutions, noting in *The Elementary Forms of the Religious Life* (1915: 60) that "there is no church of magic." In that respect, for Durkheim, 'religion' was an advance over magic because it brought people together and enhanced human solidarity. Still, traditional religion was in the process of being supplanted by a form of religion more consistent with modern society. In his contribution to the Dreyfus affair in 1901, Durkheim wrote (1973: 52) that "man has become a god for man, and … he can no longer create other gods without lying to himself." The modern 'cult of the individual' was not about egoism in the negative sense, a celebration of utilitarianism, but rather a glorification of that dignity that human beings share in common. A member of the *Ligue des droits de l'homme*, Durkheim was instead invoking the idea of human rights as a replacement for traditional religion. Yet even if traditional religion was on its way out, in Durkheim's view, every society had and would always have a sort of religious basis. This idea of 'civil religion,' first adumbrated by Rousseau in *The Social Contract* (1973), was carried forward by one of

Durkheim's most important heirs, the sociologist Robert Bellah (1991).

Weber's position on the fate of religion was more ambiguous. He viewed religion as something of an endangered species as well, but in the sense that it would be shunted into the realm of the irrational rather than that it would disappear entirely. Weber took this position against the background of a larger commitment to the idea that human history could be understood above all in terms of a process of *rationalization*. This process took many forms and, in Weber's view, was fundamental to understanding the diverse routes taken by different civilizations into the modern world. Weber's comparative studies of the world religions were titled in German *Die Wirtschaftsethik der Weltreligionen* (*The Economic Ethics of the World Religions*), signaling the degree to which they were – like so much of Weber's writing – a response to Marx's analyses of the modern world. The studies of the world religions proposed to make sense of the 'rise of the West' – that is, why modern 'rational' capitalism emerged first in the West and not somewhere else – and paid less attention to political matters, except insofar as these were thought to foster or hamper the emergence of a 'rational' acquisitive ethos. Weber held Protestantism's stress on the idea of a 'calling' and especially Calvinism's dour view of frivolous self-enjoyment to be the outlook that harmonized – felicitously if unintentionally – with the workings of rational capitalism. Yet, with his typical proclivity for irony and tragedy, Weber argued that the elective affinity between Protestant ethical doctrines (*die protestantische Ethik*) and the spirit of capitalism would lead to the construction of an 'iron cage,' one that would promote bureaucratic rationalization and thus a further strengthening of the bars of the cage. For all its rationality, Weber was saying, rationalization was a trap.

For his part, Sigmund Freud continued the Enlightenment program of enthroning reason in human affairs by proposing to replace the chaos of the human instincts with rational self-control. (In the original German, Freud used the term *Triebe* or 'drives,' not *Instinkt*; the term 'instinct' was supplied by James Strachey, the English translator of much of Freud's oeuvre. Still, the term 'instinct' has become canonical in English.) To use the language of psychoanalysis that he developed, "where id was, there ego shall be" (Freud, 1965: 71). Freud sought to tame the irrational by mapping the human mind and developing a procedure for understanding unruly, unproductive human impulses. Freud's powerful analyses held out the promise that human unreason could be reduced, if not eliminated, by understanding the past experiences that unconsciously shaped present behavior. The technique, which made talk the vehicle of mental healing, came to be known as the 'talking cure.' With regard to the prospects of Enlightenment in human affairs, Freud himself lost some heart as a witness to the catastrophic carnage of World War I in Europe. Having previously posited a 'pleasure principle' as the chief driver of human behavior, in 1920 Freud (1961a) proposed that human beings also had a 'death instinct' that was an ineradicable part of their instinctual makeup. In his most sustained and expansive reflection on human civilization, Freud (1961b) argued against socialists and others that this aggressive drive could be lessened somewhat by greater social equality, but could never be eliminated entirely. Psychoanalysis took bourgeois Europe by storm, and – despite questions about its 'unscientific' status – profoundly influenced major twentieth-century social scientists such as Talcott Parsons (see Parsons, 1982), who absorbed European intellectual culture as a young man sojourning at the London School of Economics and the University of Heidelberg in the mid-1920s. Yet in a testament to the variable forms that 'Enlightenment' took in different social settings, Freud's texts had to be translated into a scientized (Greek) language in order to gain broader favor in American circles (see Bettelheim, 1983). For better or worse, Freud's oeuvre decisively shaped the *Triumph of the Therapeutic* (Rieff, 1966).

Weber's jaundiced view of rationalization would later be taken up by two sophisticated 'Western Marxist' thinkers, themselves deeply influenced by Freud, namely Max Horkheimer and T.W. Adorno. The two thinkers of the so-called Frankfurt School of 'Critical Theory' argued in a wartime tract that the Enlightenment had doubled back on itself, so to speak, and become a sort of curse, ensnaring humanity in a self-made web of unreason. The domination of 'instrumental reason' – the sort of rationality that Weber suggested was paramount in the 'iron cage' of modernity – had deprived humanity of the ability to think in terms of 'substantive reason,' the sort that treats human beings not as means but as ends in themselves (Horkheimer and Adorno, 1972). The irony, of course, is that one of Kant's central ideas – his 'practical imperative' – had been precisely that one should "treat humanity, whether in your own person or in that of another, always as an end and never as a means only" (1959a: 47). For Horkheimer and Adorno, soured on the Stalinist version of socialism but forced to flee an anti-Semitic behemoth they regarded as an outgrowth of capitalism, the world had lost the capacity to live up to Kant's imperative.

Horkheimer and Adorno's deeply pessimistic treatise from World War II era was relatively little known in the non-German-speaking world until it was translated into English in the 1970s. At that point, however, it resonated with a broader disenchantment with Western political dominance that was then spreading among the intellectual classes that had entered university life with the 1960s expansion of tertiary education. Consistent with the Frankfurt theorists' intuitions, the Holocaust and the atomic bomb fueled worries that the scientific advances once seen as advances stemming from the Enlightenment were turning out to be the means for the extermination of the species. One of the signal contributions was that of Michel Foucault, a French thinker whose Nietzschean orientation to philosophical questions spurred an exploration of the connections between power and knowledge. Whereas earlier social scientists had typically been driven by the belief that knowledge is worth acquiring because 'knowledge is power' and could be used to 'speak truth to power,' Foucault identified subterranean connections between 'regimes of truth' and 'discourses' that sustained a seamless link between 'power/knowledge.' Foucault's work was that of a disenchanted member of the French Communist Party, long known as a 'Stalinist' party and hence not particularly interested in (or actively opposed to) his concerns with madness, sexuality, and the politics of knowledge. Foucault's politics would thus drift toward the notion of 'biopolitics,' asserting the primacy of the discourses that governed the growth and regulation of populations in the modern period. His writings would thus

resonate strongly with emerging social and intellectual movements concerned with sexuality, identity, and the like. His critique of the 'universal' intellectual associated with the Enlightenment and his advocacy of a new 'specific' intellectual fit neatly with a postmodernist critique of 'grand narratives' (Lyotard, 1984) that coincided with the shift from class politics to identity politics in the 1970s and after.

Relatively little of this philosophical controversy influenced the main body of the political and social sciences, which emerged from World War II – especially in the United States – as increasingly empiricist disciplines. The impact on the more theoretical and interpretive margins of these fields were affected, however, as was anthropology, which proved to be more open to the 'interpretive turn' then sweeping the more 'humanistic' social sciences. Behind the leadership of Clifford Geertz (see esp. 1977), James Marcus and others had drawn the field in the direction of hermeneutics and the idea that societies could be 'read' as texts or discourses. These trends drew perhaps more on the work of Paul Ricoeur (1981) than on Foucault, but the shift away from a focus on social and kinship structures was pronounced. Geertz later regretted what had been done in his name (see Geertz, 2000), but the postmodern genie and its skepticism about the Enlightenment was out of the bottle.

Not everyone was prepared to concede that the 'grand narratives' associated with the Enlightenment destined for the junk heap of history, however. Perhaps the most influential and thoroughgoing counterattack was mounted by the German social philosopher Jürgen Habermas. In a series of lectures on *The Philosophical Discourse of Modernity* (1987), Habermas trained his critical attention on a variety of German and French antagonists of Enlightenment-style critical reason. One of his principal *bêtes noires* was Foucault, whom he understood as a crucial figure in the 'counter-Enlightenment' of the last part of the twentieth century. Foucault, Habermas wrote (1987: 282–283), "does not want to refine the language game of modern political theory (with its basic concepts of autonomy and heteronomy, morality and legality, emancipation and repression) and turn it against the pathologies of modernity – he wants to undermine modernity and its language games" *tout court*. As a student of Horkheimer and Adorno whose thought has been deeply shaped by what he regarded as Germany's catastrophic twentieth-century descent into irrationalism, Habermas had little sympathy for what he saw as a flirtation with antirationalism. That this flirtation came by way of absorption with the radical antidemocrat Friedrich Nietzsche only made it more suspect.

Criticism of the postmodern turn in the social sciences also came from a somewhat unlikely source, namely Edward Said. In the 1994 'Afterword' to his widely acclaimed volume *Orientalism*, Said (1994: 349) decries the 'Eurocentrism' and 'the almost decorative weightlessness of history' in postmodern writing, seeing in postcolonial studies at least a search for structures of domination and resistance. Postmodernism, by contrast, was marked, according to Said, by "a preponderance of theoretical and aesthetic emphasis stressing the local and contingent," an unpromising point of departure if one is interested in 'speaking truth to power,' as Said himself clearly did in his critique of 'orientalist' ways of thinking.

Soon thereafter, the anti-Enlightenment tendencies in the academy came in for a more visible challenge at the hands of a New York University physicist named Alan Sokal. Perturbed at the anti-Enlightenment trends in intellectual life and a self-described political progressive, Sokal set out to see whether he could persuade a major journal of the newly emerging field of 'cultural studies' to publish "an article liberally salted with nonsense if (a) it sounded good and (b) it flattered the editors' ideological preconceptions" (Sokal, 1996b). He could; *Social Text* accepted the article, apparently without serious evaluation by knowledgeable scholars as would be standard practice for a peer-reviewed scholarly journal. The aftershocks were not to remain confined to the ivy tower. The ensuing controversy was played out in the pages of academic journals and on airwaves. The editors of *Social Text*, among the more prestigious scholars in the world associated with cultural studies and post-modernism, suffered a rather serious black eye, as did the intellectual currents with which they were associated. That is hardly the same as saying the trends they represented and promoted would disappear, however.

Indeed, the discomfiture with the Enlightenment, with ('Western') modernity, and with the supposed failings of 'reason' has persisted. One of the most vigorous critics of this cultural vein in recent years has been the neuroscientist Steven Pinker. Best known for his writings on cognitive psychology and linguistics, in 2011 Pinker published a massive study arguing – against considerable evidence to the contrary – that violence had declined in the modern world as compared to the earlier societies in which no state held a "monopoly on the legitimate use of violence" (Max Weber's famous definition of the state). According to Pinker (2011: xxii), "a large swath of our intellectual culture is loath to admit that there could be anything good about civilization, modernity, and Western society." Pinker's book was perhaps as much directed at this audience as it was at students of violence in the modern world. Whether he is correct about the decline of violence on a world scale remains a matter of considerable debate; the judgment depends significantly on the reliability and generalizability of evidence of intrinsically recondite character (see Lawler, 2012).

But the effort to establish whether, against all appearances and our intellectual prejudices, violence has actually declined with the shift to state-dominated societies constitutes one of those quintessentially social scientific questions bequeathed to us by the Enlightenment. We cannot presume to know the answer without investigation and thoughtful weighing of the difficult evidence. We must dare to use our reason. That is surely what the modern social sciences understand themselves to be doing, even if there have been doubts along the way about whether that reason is as disinterested as it imagines or as helpful to the human species as its practitioners believe.

Abstract

Entertainment is defined as play put on display. The etymology of the word points to the inner connection between entertainment and community. A map of the world of entertainment is sketched out, based on the oppositions between identification and alienation and between activity and passivity. It is shown how entertainment has a history leading from the festivals and spectacles of antiquity through medieval carnival to courtly diversions. The nineteenth century is described as the age of modern mass entertainment, and it is shown how in the twentieth and twenty-first centuries, the interplay between entertainment and urbanization gives rise to shopping malls and entertainment cities. The article ends with a note on the globalization of entertainment.

Entertainment is play, but play put on display. In the modern, Western or Westernized world, plays and games have become commodities for sale in that special branch of economic life called show business. There is no limit to the media, art forms, or genres to be marketed by the agents of show business, but the term 'light entertainment' marks the quintessence of entertainment: ease, glitter, and lightness. Entertainment has no other aim than to please as long as 'the music plays.' In 1844, *Tivoli-Avis*, the newspaper of the Tivoli Gardens, the amusement park that was established in 1843 on the military fortifications around Copenhagen, stated that "Tivoli produces only one thing: joy!" (Zerlang, 1997: p. 97). In 1957, an advertisement for the newly founded Disneyland called it "a new industry with happiness as its principal product" (Findlay, 1992: p. 75). Entertainment, in the modern sense of the word, may thus be defined as the commercialization of the pursuit of happiness.

Entertainment and Community

The pursuit of happiness has no doubt been a primary driving force of mankind since the beginning of time. One of the ancient Greek philosophers, Democritus, once stated that without festivity life is like a long road without an inn, and during the apogee of the Classical Athenian era, more than 40 feasts and festivals were celebrated every year. Arranging the festivals was a public office of the highest importance. Festivals also play a major role in Plato's description of the ideal state, because they are community building: "There is no greater good in a state than that the citizens should be known to one another" (Laws, 738).

The word entertainment actually refers to social exchanges. It is derived from Latin: *inter* means 'among' or 'between,' and *tenere* means 'to hold something mutually' or 'to keep something up.' Thus, entertainment is a social relationship and it is concerned with social relations. In premodern times, entertainment primarily indicated material support; with modernization, entertainment is about spiritual support. Support is another word for something uplifting. Listeners to happy jazz or pop songs expect 'to get carried away' by the ease of pop ballads or the swing of jazz music. And the meaning of dance is a temporary stepping out of the world of everyday life.

Happiness is uplifting; in an unhappy state of mind, one feels down. The individualism of modern culture has traditionally been accompanied by the problem of boredom. During the nineteenth century, writers repeatedly described and deplored boredom, spleen, ennui and Langeweile, and one of the pioneers of modern entertainment, the composer Jacques Offenbach, emphasized the importance of mutual support by declaring that his dream was "to found a share holding company of mutual insurance for the prevention of boredom" (Kracauer, 1976: p. 101). In his operetta *La vie parisienne* (1866), Offenbach celebrates and satirizes the collective festivity at railway stations, hotels, exhibitions, cafés, parties, and masked balls. Individual unhappiness disappears in the crowd.

Mapping Entertainment

Mapping the world of entertainment may start by a reflection on the expression: 'only entertainment.' If entertainment is 'only entertainment,' this indicates two things: that entertainment has become a specific field of activity and that entertainment has no importance; it is 'just fun.' As a specific field, as 'show business,' entertainment differs from play, although it is based on forms of play. And as a sphere of activities allegedly of no importance, entertainment differs from art, although it apparently enjoys the same autonomous status. Kant, who characterized the aesthetic attitude by its 'disinterested pleasure,' would consider the search for laughs, thrills, tears, and sex as 'interests' that would degrade entertainment in relationship to art. Others fulminated against the reduction of serious art to an entertaining commodity. A symptom of the great divide between art and entertainment that developed during the nineteenth century is Robert Schumann's reaction to the new, immensely popular waltz music: he wrote that he heard the gold rattling in Strauss Sr.'s pocket as he conducted.

The reduction of entertainment to 'only entertainment' may be interpreted as an effort to deny or exorcise the real importance of entertainment in modern society: as a substitute for religion, as a purveyor of a new mythology, as a political element, and as a key sector in the economy.

The question now is whether it is possible to see a pattern behind all the variety. In the same way as play may be divided

into a clear pattern of categories, the forms of entertainment may be organized according to the way in which they express the relation between individual and society. According to Roger Caillois (1967), games may be classified into four main headings based on different ways of handling the oppositions between identification and alienation and between activity and passivity.

1. The first pole is 'agon,' competitive entertainment based on active identification. Here one finds not only chariot races, chivalrous tournaments, and sports but also narratives of action and adventure whether told in novels, films, television (TV) shows, or computer games. The hero seeks recognition of his identity, and the audience identifying with the hero seeks recognition in his victory. The characteristic emotional experience of competitive entertainment is suspense, which gives the reader or spectator a vicarious, but intense bodily feeling of taking part in the action. Open spaces often characterize the world of 'agon.'
2. The second pole is 'alea,' the entertainment of chance based on passivity and identification. Here, one finds not only all games of chance but also stories of horror. The hero is more often than not a victim, and if he ends up as winner it is not by his own merit. Identification does not consist in recognition of his name, but identification of the number that makes him a winner – or victim. The characteristic emotional experience is the thrill that gives the reader or spectator a vicarious feeling of being victimized or saved by alien forces. Closed spaces often characterize the world of 'alea.'
3. The third pole is 'mimicry,' all kinds of theater, tableaux vivants, masquerades, variety shows, parodies, etc. The hero takes on a heroic, villainous, or just different persona, and if he gains a name, it is through this talent for impersonating. By definition, the whole gamut of emotions is invoked by this type of entertainment. As is obvious in melodrama, thresholds often energize this kind of entertainment.
4. The fourth pole is 'vertigo,' the high-spirited pleasures of a temporary suspension of one's everyday identity, promoted by roller coasters and swings, by waltzes and rock-n-roll, and by comedy. Here, the hero hands himself over to impersonal forces, but in contrast to the gambler, he does not look for any profit but the pleasure of vertigo. Even though emotional distance from the capers of clowns of all sorts is one of the enjoyments of comedy, the readers or spectators who give themselves over to laughter are also looking for the pleasure of letting go and losing control.

Bread and Circuses

In Western culture, the concepts of spectacle and circus go back to antiquity. The idea of the ludic, i.e., the playful, is derived from the Roman concept of *ludus* (chariot races); and the idea of the aleatory, i.e., gambling with chance, is derived from the Roman word for dice. In the course of Roman history, religious rituals – such as gladiatorial fights in connection with funeral rites – are restructured into cultural forms much closer to the modern idea of entertainment. In the tenth of his satires, Juvenal coined the phrase 'bread and circuses,' and this verdict on a social policy replacing the active political commitment of the citizens by their passive reception of material and mental entertainment has been an inspiration for modern cultural critique. According to Patrick Brantlinger, equating the social decay of the Roman Empire with the 'massification' of modern society constitutes a 'mythology of negative classicism.' However, seeking parallels between the ancient and modern worlds was not the preserve of critics. The founding fathers of modern entertainment also cultivated the Roman or classic connection: The great panorama building erected in London in 1827 was called the Colosseum. Las Vegas still boasts a Caesar's Palace.

Carnival

In the middle ages, Roman festivals such as the Saturnalia and Lupercalia metamorphosed into the extant tradition of carnival. Entertainment is often characterized as recreation, and recreation is what characterizes the carnival. The rural and pagan carnival would re-create the natural world, the Christian world would re-create the religious community, and the urban carnival would re-create the power and splendor of the city. The world is turned upside down, boys become bishops, men dress up as women, and processions carry gigantic sausages through the streets, and in this creative chaos, the sense of community is reanimated.

In contrast to commercial entertainment, those taking part in the carnival were not free to choose their leisure. Even if the carnival was entertaining, it was not pure entertainment. People were not individuals buying a ticket to a show, but members of a community obliged to follow the calendar. Shrovetide was a once-a-year experience.

From the perspective of the church or the city council presiding over the carnival, the aim of the event was to make the different groups of society accept the existing hierarchy. The creative chaos was also a deterrent. The blasphemous words, the mock battles, etc. would illustrate the consequences of real social change.

The authorities could use the carnival. That is the only plausible explanation of their pivotal role in staging the processions and plays of the carnival. But as long as the carnival lasted, the situation was potentially open, the functions and the future of society were put at stake, and the safety valve might turn into an explosive risk.

In his influential book *Rabelais and His World* (1968), Mikhail Bakhtin emphasizes the emancipatory aspects of the carnival. To him it exalts the people versus those in power, the lower social and bodily strata versus the repressive idealism of official culture. In *Le Carnaval de Romans* (1979), Emmanuelle Le Roy Ladurie closely analyzes one specific carnival, in the year 1580, and here the sources tell about the confrontation between disciplining forces and rebellious forces within the carnival.

Courtly Diversions

In the fifteenth and sixteenth centuries, a process started in Europe during which the paths of popular culture and elite culture diverged. Politically, as power became centralized, the powerful made a spectacle of themselves through fireworks,

pageants, and allegorical plays while reducing their subjects to spectators. Economically, the reformation and the rise of the middle class, who knew that time was money, was accompanied by a war against idle leisure.

To the aristocracy as well as the middle classes, the experience of time, the abstract time of the clock, became a new social experience, but while the aristocracy actively cultivated a culture of pastimes and diversions, the puritan middle classes rejected all pastimes that would divert their attention from work. While the aristocracy indirectly became the pioneers of modern entertainment, the puritans just as indirectly created the patterns of modern cultural critique.

The culture of *divertissements* at the French court developed as the process of centralization and the politics of absolutism transformed the 'nobility of the sword' into courtiers. Leisure time at the court became a psychological as well as a political problem. To aristocrats used to fighting, hunting, etc., life at court was inactive and boring, and they had to do something to pass their time. Diversions would compensate for the lack of activity and power, and entertaining discussions and dances, etc. would at the same time create a social bond between them. The intricate equestrian displays known as *carrousels* epitomized this domestication of a warrior class through entertainment. A trace of this phase in the history of entertainment may still be seen in the predilection for a lavish, baroque style in merry-go-rounds and other fairground architecture.

Commerce and Buying Fun

In the eighteenth century, the word entertainment (or in German: *Unterhaltung*) had a breakthrough, but this was in reference to private or domestic entertainment. Private evening entertainment would include music, dance, and the creation of *tableaux vivants*, but it was the expansion of the book market that really made the home a center of entertainment. This market became the great provider of entertainment, and these entertainments were open to everyone with sufficient means. In 1725, Daniel Defoe noted that writing had become "a very considerable Branch of the English Commerce" (Watt, 1957: p. 55), and an increasingly popular genre such as 'the penny dreadful' indicates the importance of the market. In the Scandinavian languages, the word commerce became synonymous with having fun.

Traditional entertainments did not disappear from 1 day to the next. At the beginning of the nineteenth century, Joseph Strutt wrote *The Sports and Pastimes of the People of England* (1801) in which it is obvious that the idea of public entertainment for the general public was only beginning to get a foothold. In his table of contents, the pastimes are divided according to time, place, and social group: 'Rural exercises practiced by persons of rank,' 'Rural exercises generally practiced,' 'Pastimes usually exercised in towns and cities, or places adjoining to them,' 'Domestic amusements of various kinds; and pastimes appropriated to particular seasons.'

In contrast to premodern entertainments, the break with hierarchy was a general feature of the modern culture of entertainment. When Philip Astley founded the first circus at Westminster Bridge in 1770 (Speaight, 1980) – gathering itinerant showmen, jugglers, clowns, and acrobats under the same roof, with riding masters as a tribute to aristocratic culture – he addressed his public 'the Nobility, Gentry and others.' But he, as well as other entrepreneurs within show business, soon learned that it would pay off to put the 'others' in the foreground. If the new entertainment industry used amusements of the old aristocratic culture, this would inevitably democratize the diversions of the past. Søren Kierkegaard made 'leveling' a key concept in his analysis of modern, urban culture just as Georg Simmel wrote of 'leveling' in his analysis of *The Metropolis and Mental Life* (1903).

The Mass Entertainment Industry of the Nineteenth Century

According to Asa Briggs, five conditions stand out as necessary for the development of a mass entertainment industry in the nineteenth century: (1) a large and concentrated urban population; (2) sufficient money to buy regular, cheap entertainment; (3) sufficient leisure time to make a commercial exploitation possible; (4) urban transport systems to take the public to the places and palaces of entertainment; and (5) the application of technology to entertainment.

Jacques Offenbach's *La vie Parisienne* may be said to illustrate these five preconditions for the rise of a mass entertainment industry: as the title indicates, the setting is Paris, and the action starts on one of the new railway stations of Paris. The cast of characters either has plenty of money or knows how to get money. The storyline revolves around a new social group, the tourists, and they of course have sufficient leisure time. To re-create the spectacular glitter of modern Paris on stage, the theater would have to apply the newest technologies of stage lighting, etc.

In the nineteenth century, the concentration of the urban population was preceded by an uprooting of people – from the countryside, from tradition, etc. – and the isolation of the individual in the middle of the urban crowd created a need for entertainment to provide psychological support. Just as the popular culture of fairy tales, carnival, etc. had given form and meaning to the culture of preindustrial society, the mass entertainment industry created a sense of community among urban dwellers who could no longer rely on time-honored traditions or preestablished social relations. Boredom may be termed the cultural disease of the nineteenth century. Similar to the boredom experienced at the courts of the seventeenth and eighteenth centuries, this was the psychological reflection of a loss of cultural meaning, a loss of a common cause. A recurrent theme in nineteenth century literature was the characterization of boredom (ennui, Langeweile, …) as a modern invention, a modern monster, the constitutional evil of the century (see Sagnes, 1969). In 1843, the same year that the cosmopolitan Georg Carstensen opened the Tivoli Gardens in Copenhagen, Søren Kierkegaard published his *Either-Or* (1987) with an ironical chapter on boredom as the source of all creation, including the Creation, and as a remedy to this boredom, he suggested public entertainments on a grand scale.

The grandest scale was represented by the city itself, and the crowd and urban life became a leitmotif in all kinds of modern entertainment: panoramas such as the London Colosseum showing a panorama of London as seen from the cupola of

Saint Paul's Cathedral, crime and detective stories, melodramas, and the 'sounds of the city' in the music halls.

Many of the new establishments of entertainment were even constructed as small cities, for instance, panoramas with their spectacular 360° representations of cityscapes, world exhibitions, as well as amusement parks and zoological gardens with gates, walls, streets, squares, and animals living in cages shaped like buildings from their native countries.

City life was entertaining in itself, as witnessed by cafés, promenades, show windows, etc., and the appeal to visual pleasures was noticed by most observers. Charles Lamb (1906) wrote of the spectacle as the essence of the city; Théophile Gautier (1858–59) declared that the era of purely visual spectacles had arrived, and in the 1880s, a new and abundant use of the terms 'show' and 'show business' (see Nasaw, 1993) marked the visual turn of entertainment, which has continued with film, TV, and even music videos into the twentieth and twenty-first centuries.

Variety

Distraction is an important aspect of entertainment, and diversity or variation has since time immemorial been a key to entertaining performances. In *A Short History of Western Performance Space* (2003), David Wiles traces the pleasures of variation back to the symposia of Ancient Greece. Thus, Xenophon describes a symposium hosted by a rich Athenian, where the audience was entertained by instrumental music, juggling hoops, acrobatics, a boy's athletic dance, a boy singing, and a mime play. In contrast to the art of the theater, which was characterized by its unity and its cathartic function, the symposium would offer a variety show in connection with culinary pleasures.

At the founding of music halls in the middle of the nineteenth century, there still was an inner connection between dining, drinking, and variety shows. As indicated by the word 'café,' coffee was part of the entertainment at the café concert and the café chantant, and similarly the posters by Toulouse-Lautrec show the role of sparkling champagne in 'la belle époque' (1890–1914) when the world of entertainment became an inspiration to the avant-garde.

Entertainment also contributed to the so-called postmodern art, and already in 1957, Roland Barthes with his essays in *Mythologies* sketched out some of the features that would inspire postmodernist artists. In his essays on the music hall, he gives a succinct version of the aesthetics of the spectacular. According to Barthes, variety emphasizes the pleasures of the moment, the present moment. The variety show celebrates the body and its gestures, and it cultivates the purely visual beauty of the perfect gesture. All the hard training preceding the 'turns' in a show is not part of the aesthetics. Lofty ideals do not count in this world of the perfect gesture of the acrobat and the imperfect gestures of the clown. And in this urban world of glittering diversions, attention is diverted from boredom, at least for the moment.

Funscapes

In *Sous couleur de jouer* (1989), a philosophical essay on the meaning of play, Jean Henriot argues that behind all the historical and cultural variations in meaning there is a common ground reflected in the use of 'jeu' or 'play' within a mechanism. Here play indicates a space with room for motion, especially rapid, brisk, and light movement, a more or less open interplay between forces.

As an illustration, Henriot quotes Friedrich Nietzsche, who in *Thus spake Zarathustra* talks about play as a "self-rolling wheel, a first movement" (Henriot, 1989: p. 91). In fact, the wheel, the round shape, and the curvilinear are ubiquitous in the world of entertainment. The ring of a circus, the curves of a balloon, the turns of a merry-go-round, the loops of a roller coaster, a Ferris wheel, and a panorama all celebrate relaxation and pleasure, in contrast to straight lines as symbols of strict rationality.

In 1785, William Cowper expressed his concern that balloons would cause 'the annihilation of all authority,' but in 1870, when Fulgence Marion wrote his book on *Wonderful Balloon Ascents*, all worries were overcome. He noted the 'familiar appearance' of the balloon, adding that this form afforded an appropriate symbol of the balloon's own characteristics: "… a harmless, placid, even attractive object, floating serenely and unconcernedly in the sky, subject always to the whims of changing currents or the mercy of strong winds, and carried here or there or (in a calm) nowhere …" (Freedgood, 1997: p. 62).

In his book *The Power of the Center*, Rudolf Arnheim observes that "roundness is the suitable shape for objects that belong nowhere and everywhere" (Arnheim, 1982: p. 115), and he calls the spherical and circular objects 'privileged foreigners in our midst.' In *Amusing the Million* (1978), John Kasson describes how the 'barrels of fun' that would take the immigrants to Coney Island, turning them upside down, and forcing them into close physical contact, would effect a very literal process of cultural integration.

The S- and U shapes of the arabesque also became a symbol of modern show business. The German writer Friedrich Schlegel declared the arabesque to be the oldest form of human imagination, and he claimed that "the suppleness of its line and its caprice are able to embrace the twists and turns, the spontaneity and chance encounters, of life itself" (quoted in Gordon, Ornament 33). The arabesque was of course closely connected to the Orientalism that during the nineteenth century became a way of framing entertainment – in theaters, music halls, etc. The arabesque combined escapism and experiment. The world of entertainment offered its visitors an escape from the routines of everyday life, but at the same time, it challenged them to deal with other cultures, other ways of life.

Owen Jones, who was one of the designers of the Great Exhibition in 1851, also published a book on *The Grammar of Ornament* (1868). Here he suggests that the arabesque may be interpreted as an invitation to stop and linger. In the midst of an ever more stressful urban life, these patterns would seduce the visitor or customer into enjoying an ambience of luxury and balance: "We have lines running horizontally, perpendicularly and diagonally again contrasted by circles in opposite directions. So that the most perfect repose is obtained, the tendency of the eye to run in any direction is immediately corrected by lines giving an opposite tendency, and wherever the eye strikes upon the patterns it is inclined to dwell."

Entertainment Cities

The nineteenth century was intoxicated with expositions, the French writer Gustave Flaubert observed, and nothing was more intoxicating than the world's fairs. During the summer and autumn of 1851, the Great Exhibition in London, especially the gigantic Crystal Palace, attracted more than 6 million visitors. According to Gustave Flaubert, the nineteenth century was delirious with exhibitions. Hans Christian Andersen, who visited the world's fair in Paris in 1867, wrote a 'modern fairytale' on this exposition, in which he introduced the concept of 'knick-knacks of greatness,' which very precisely indicates the principle governing world's fairs: scale reduction. If the world is put into a nutshell, it becomes perceptible and manageable; if the big world is the cause of fear, the little world is a source of fun. World's fairs became major institutions of entertainment, and at the same time they acquainted their huge audiences with new technologies of entertainment such as the Ferris wheel.

In nineteenth century Europe, around the middle of the century, the ineluctable process of urbanization made it necessary to tear down the walls and gates around the cities, but feelings of insecurity during the expansion were countered by the construction of amusement parks, zoological gardens, department stores, etc., as 'cities within the city.' Tivoli Gardens in Copenhagen was established on the military fortifications 15 years before the decision to demolish the ramparts, and in many respects, this amusement park may be interpreted as a harbinger of modernity. At the same time, however, the cultivation of the small scale, the rails around the park, and the impressive gates leading into the park, all pointed backward, nostalgically, to the era of walled cities.

Tivoli Gardens was an important inspiration to Walt Disney, whose Disneyland opened in 1955. In contrast to the diversity of the Tivoli Gardens, however, Disneyland was much more structured. It was the first theme park, based on the characters from Disney's cartoons and movies, but divided into five subthemes: Main Street, Adventureland, Fantasyland, Tomorrowland, and Frontierland. As banners make explicit, the motto of 'Disneyland' was and is 'Safe, Clean and Fun,' and the ideals of this entertainment utopia suggest its background in cultural currents of the 1950s. It capitalized on the ongoing 'White Flight' into the suburbs, on the fear of the impending atomic bomb, and it celebrated the nuclear family and 'the American Way of Life.' Disneyland was designed to wall off people from the outside world (Findlay, 1992: p. 54), and its creators, having learned from movie and TV designers, succeeded in creating what has been called "less an amusement park than a state of mind" (Findlay, 1992: p. 66). Critical commentators, however, have pointed to the interplay between entertainment and containment, between free fantasy and cold control in this utopia.

Disneyland was created at the same time as the Austrian-born architect Victor Gruen created the first shopping malls, and inside these closed architectural structures, shopping developed into a new kind of entertainment. In the words of Michael Sorkin, the shopping malls became 'variations on a theme park.' In the 1980s, Jon Jerde took over as the leading shopping mall environment architect, and he not only integrated various kinds of entertainment into shopping but also applied the playful and seductive architecture of amusement parks to his malls: curved balconies, crossing staircases, flashy colors, and reflecting surfaces.

Cities such as Los Angeles/Hollywood and Las Vegas base their economies on entertainment, but even here a kind of second-degree reference to the world of entertainment serves as an instrument of moneymaking. In 1993, Jon Jerde opened a miniature city, Universal City Walk, in Hollywood, based on film sets and well-known movie locations such as Melrose Boulevard, Sunset Strip, and Venice Beach. At the same time, in real cities, show business reshaped time-honored urban spaces. Disney put his stamp on Times Square in New York and in postwall Berlin Sony gave Potsdamer Platz its new identity.

Globalization of Entertainment

Entertainment has played a major role in the globalization of culture. Around 1900, Coney Island helped immigrants to adapt themselves to American culture, and at the same time American vaudeville – as Albert McLean puts it – became a ritual that allowed immigrants to articulate or interpret their experiences in the new country. In his book *Movie Made America* (1975), Robert Sklar follows this line of thought, but not only did Hollywood 'make' America. It also became a worldwide business. On one hand, Hollywood offered entertainment on a global scale and on the other hand, Hollywood appropriated entertainment from the rest of the world. An obvious example is the genre of Kung Fu movies. In 1974, Carl Douglas made a hit with his song 'Everybody was Kung Fu fighting,' and indeed since the 1970s the entertainment industry of Hong Kong has exported directors, actors, stories, and styles to Hollywood while Hollywood, at the same time, has influenced film making in Hong Kong and the rest of the world. Nicknaming the film industry in India 'Bollywood' reveals this close encounter of the first degree between local and global entertainment cultures.

Entrepreneurship and Economic Growth

Abstract

Entrepreneurs, creators of new firms, benefit economies in several ways through innovative activities, new job creation, increased productivity and competition, or because they accelerate structural change. Without new entrepreneurs and the businesses they create, economies may stagnate. Therefore, new business formation by entrepreneurs is regarded as one source of innovation and economic growth.

Introduction

The activities of entrepreneurs are considered to be one important driver of economic dynamics. Entrepreneurs generate employment opportunities not only for themselves but also for others. Beyond the job creation, entrepreneurial activities may influence a country's overall economic performance in several ways: (1) entrepreneurs enter markets with new products, technologies, or production processes; (2) they increase productivity and competition; and (3) they accelerate structural change. Without new entrepreneurs, economies may stagnate.

Despite these apparently important roles in the economy, mainstream economic research generally ignored entrepreneurship for half a century (Barreto, 1989). Only in the 1990s it started that entrepreneurship was recognized as a critical part of successful economies. Researchers in economics, psychology, sociology, and management gradually became interested in entrepreneurship, which is mirrored not only in a growing number of field journals on entrepreneurship, but also in statements such as of Ed Lazear who claimed that "the entrepreneur is the single most important player in a modern economy" (Lazear, 2005: p. 649). This recognition did not happen by chance; it was triggered by substantial changes in the real economy where, in particular, the developments in the information and communication technology sector lead to an expansion of entrepreneurship in developed economies (Audretsch and Thurik, 2000).

At the same time, the media became enthusiastic about entrepreneurs, as well. Frequently incredible success stories of entrepreneurial heroes are featured on television and in magazines. The protagonists change, but the story line remains the same. Obsessed by their business idea, entrepreneurs make risky decisions every day and bear the consequences of these decisions. They are able to swallow any kind of setbacks and, if necessary, they are willing to mortgage their homes, and at the end of the story they become billionaires. The question arising from the scientific point of view is whether these icons serve as role models of the 'perfect entrepreneur' and, if so, whether such role models are helpful, as they may make the majority of potential entrepreneurs feel inadequate in comparison.

In this vein, only a minority of individuals become entrepreneurs: in highly developed economies like the United States, Sweden, and Germany, only one or two out of every 100 individuals in the working population will start entrepreneurial activities in a given year. Thus, the entrepreneur is rare and while some argue that they are important for economic growth and performance, others warn that we run the risk of overstating the impact of entrepreneurship and that we should not try just growing the number of entrepreneurs *ad infinitum* (Shane, 2009).

Given the increasing discussions about entrepreneurship, this contribution will start by defining who are entrepreneurs and what they do. Then the typical determinants of entrepreneurs are revealed, focusing on the socioeconomic, human capital, and personality characteristics that influence the decision to become an entrepreneur. This endeavor will also allow answering the question to what extent the above presented role model and personality characteristics are found in research findings. Based on these definitions and concepts, it is then shown how entrepreneurial activities may affect an economy.

Concepts and Definitions: Who Are Entrepreneurs and What Do They Do?

When describing what entrepreneurs do, we may come up with the following description: Individuals entering entrepreneurship need to identify and exploit opportunities. For the exploitation they typically produce a technology, a good, or service that may involve some form of innovation. More specifically, at every step of the production, marketing, and selling process of their specific product, the decisions they make will determine whether they start their business, and, assuming they do, whether it will succeed and create the maximum value possible. These decisions range from the basic quality and quantity of production, determining investments in the business, deciding upon a marketing strategy, understanding the competition, and, ultimately, delivery of their product to the client. Thus, entrepreneurs need to do many things, or, as Lazear (2005) notes, they need to be "jacks-of-all-trades." In this process, entrepreneurs make a large number of decisions, sometimes quickly, under risk or even uncertainty. Then, after decisions are made, they need to be sufficiently emotionally stable to tolerate the time span until the goods and services they have produced are actually sold. Hence, entrepreneurs need not just knowledge, expertise, and professional

competencies, but also a variety of skills and abilities that are influenced by their personality.

Over the last 300 years various aspects of entrepreneurial behavior have been captured by various scientists. The first author referring to the entrepreneur as an important actor in the economy is Cantillon (1755), who explains why a French word came to define the behavior. In his theoretical work, Cantillon identifies three types of economic agents who differ by the functions they perform: financially independent landowners, risk-taking entrepreneurs, and risk-averse hirelings who prefer stable income over active decision-making. In this setting, entrepreneurs engage in market exchanges to maximize their profit at their own risks.

Based on Cantillon's approach, a century later Say (1803) enlarged the definition of Cantillon and focuses more on the managerial capabilities, as he argues that an entrepreneur is an economic agent who unites all means of production (land, labor, and the capital) to make a product. By selling the product in the market he is able to pay for the production factors – rents, wages, and interest – and keeps the remains as his profit.

A more intensive discussion about definitions of entrepreneurship started in the twentieth century. Basically, there are three classes of definitions, also clarifying the variety of functions an entrepreneur may take: (1) those who focus on entrepreneurship as an occupational choice; (2) those who aim to capture entrepreneurial behavior; and (3) those who have the consequences of entrepreneurial activities for the economy in mind. Restricting to the most important contributions, the occupational choice definitions refer to the decision whether individuals prefer to work for somebody else or for their own account by becoming self-employed. In this context, a broad definition of entrepreneurs includes those persons who create new ventures, or more specifically who are the founders, owners, and managers of an organization under their own liability – mostly small firms where the decisions are made by the entrepreneurs themselves. Given that this definition covers anybody who starts a business, a further step is to distinct between 'replicative' and 'innovative' entrepreneurship, with 'innovative entrepreneurs' being those who bring new products and processes to the market, and introduce new kinds of services, marketing techniques, or business structures. 'Replicative entrepreneurs' are those who enter existing markets trying to have unique selling propositions in order to distinguish themselves from existing firms. Baumol (1993), one of the leading economists in this field, describes innovative entrepreneurs as the bold and imaginative deviators from established business patterns and practices.

Definitions of the second type originate with Knight (1921) and basically focus on the issue of decision-making. Knight argues that investment decisions of entrepreneurs are uncertain and that entrepreneurs have to be able to bear this kind of uncertainty. With this definition, Knight also established a central distinction between risk (which is calculable and, thus, could be covered by insurance, given that there is an underlying probability distribution for the entry of each possible outcome of an investment) and uncertainty (which is incalculable as it has to be handled with no further information) where the entrepreneur directs his actions to new and unpredictable paths. Given this definition, many scholars speak of the 'Knightian uncertainty.' Beyond issues of risk-taking behavior, another strand of behavioral approaches focuses on the specific talents an entrepreneur needs. Beyond Lazear's idea of the entrepreneur as 'jacks-of-all-trades,' earlier models like the one of Lucas (1978) highlight their different 'talents for managing' as the central explanatory variable in determining the choice of becoming an entrepreneur or, like Holmes and Schmitz (1990), who point to the ability to 'respond to opportunities for creating new products that arise from technological breakthroughs' as the crucial talent needed to become a *successful* entrepreneur.

The most important protagonist of the third class of definitions is Schumpeter, who asserts a central function to entrepreneurs in capitalist economies. According to his approach (Schumpeter, 1934), entrepreneurs are the innovators in an economy who 'carry out new combinations' and thus initiate what Schumpeter calls the process of creative destruction where old established firms and products are replaced with new firms with better or new products. More recent researchers, such as Leibenstein (1968) and Kirzner (1973), give a slightly different role to the entrepreneur in the economy. Here, the entrepreneur is able to identify and exploit opportunities by revealing inefficiencies, either among existing firms and organizations (Leibenstein), or from market imperfections (Kirzner). In their definitions, the entrepreneur is more of an arbitrageur who takes advantage of the observed gap by combining resources in a better way, by organizing the production in a more efficient way, or by producing new products or services (the latter definition being similar to Schumpeter's approach). In particular, Schumpeter's idea of creative destruction was later on formalized in models (as of Aghion and Howitt, 1992) where innovation evolves following a certain stochastic process dependent on the amount of investments in research and development (R&D). These models, however, replace the person of the entrepreneur by the amount of resources devoted to R&D activities.

Thus, there is a wide variety of definitions and concepts of entrepreneurship that are proposed. To condense these three classes of definitions, we may conceptualize entrepreneurs as individuals who are willing and able

1. to start and own an organizational entity with the purpose of creating value;
2. to innovate by identifying and exploiting (new) opportunities in the market; and
3. to bear the risk of introducing (new) products in the market as well as to manage their firm by deciding on the use of resources, production methods, and locations.

In this context, it should also be clarified that part (1) of this definition contains a limit. The establishment of a firm (an organizational entity) implies that other kinds of entrepreneurs like 'intrapreneurs' and public entrepreneurs are not included. These groups deserve separate approaches. Moreover, the purpose of creating value incorporates two groups of entrepreneurs, those who aim to maximize profit by creating value and another group that recently gained substantial attention, namely the so-called social entrepreneurs who are rather interested in value- instead of profit-maximizing.

Who Becomes an Entrepreneur and Who Succeeds?

Much effort has gone toward trying to uncover who will engage in entrepreneurial activity and who will not. Researchers have investigated which demographic and socioeconomic characteristics, as well as which personality characteristics influence the probability of becoming an entrepreneur.

Empirical analysis reveals some common characteristics in many countries when focusing on the influence of sociodemographic variables such as age, gender, and education. Starting with a person's age and the probability of becoming an entrepreneur, this relationship is inversely U-shaped. This means that the propensity of individuals to become an entrepreneur first increases with age, peaks at ages between 35 and 45 years, and then decreases again (Levesque and Minniti, 2006). While the increasing proclivity for entrepreneurship during younger ages can be explained with growing experience and an improved access to resources, the declining part may be induced by decreasing risk tolerance and the fact that individuals who have an openness for starting an own business, mostly decide to do so before they become 'too old.' This also makes clear that, for most individuals, the entry decision into entrepreneurship is not a once and for all decision at the beginning of their working career, it mostly happens after having gained 10 years of working experience (or more) as a dependently employed individual.

Second, females have a lower probability of becoming entrepreneurs than males, which may be explained by gender-specific role models, a difference in the willingness to take risks (Caliendo et al., 2014b), and the willingness to turn entrepreneurial intention into implementation (Haus et al., 2013). Third, the family surrounding influences transitions into entrepreneurship: Having self-employed parents significantly increase the likelihood of becoming an entrepreneur, perhaps because they are role models for occupational choices or because the children inherited the 'right skills and abilities' for entrepreneurial activities. Fourth, another source inducing changes to entrepreneurial activities is the amount of start-up capital available to the potential business founder. Blanchflower and Oswald (1998) show that there is a positive effect on this transition: Individuals with higher capital endowment have a higher probability of becoming an entrepreneur. Fifth, in many countries there is a positive relationship between entrepreneurship and working in the service sector, which reflects the relatively small average size of service-sector firms and lower barriers to entry in many parts of the service sector.

One important difference between countries and entrepreneurship is found with respect to educational levels. There are some countries with a linear positive relationship between having achieved higher formal qualifications, such as tertiary education or vocational training, and the propensity for starting entrepreneurial activities, while for other countries this relationship is U-shaped, meaning that lowly and highly educated individuals have a higher propensity to get involved with entrepreneurship than individuals with medium levels of education (e.g., Borjas and Bronars, 1989).

Beyond the question of how demographic and other exterior characteristics, such as capital endowment, guide the decision to start a business, there is also a discussion on the influence of personality traits on becoming an entrepreneur. This approach has been criticized by researchers for various reasons. One critique is that entrepreneurship is determined by a wide variety of factors and that the diversity in personality traits *among* entrepreneurs is much greater than differences *between* entrepreneurs and nonentrepreneurs such that it is impossible to determine the personality profile of a typical entrepreneur. Moreover, previous research tried to construct an average entrepreneurial profile, but failed to do so, as Aldrich (1999) made clear. He claimed that this kind of research had reached an empirical dead end.

Given these critical observations, recent research stopped comparing the stock of entrepreneurs with the stock of people in another employment status (see, e.g., Rauch and Frese (2007) for such comparison), but started to analyze to what extent personality influences entrepreneurial decisions at certain points in time, like the decision to quit a job and become an entrepreneur. These new approaches reveal how personality is, for instance, related to the selection into entrepreneurship without arguing that these characteristics are also important for other entrepreneurial decisions; thus they explicitly refrain from trying to construct an average entrepreneurial profile.

The most important personality characteristics that are found to influence the entry decision into entrepreneurship are the following: (1) risk attitudes, (2) openness for experience, (3) locus of control, and (4) extraversion. A closer look at these personality characteristics and their potential influence on the decision to start an own business makes clear that they all relate to the definitions of entrepreneurship discussed in the previous section.

Obviously, the outcome of each investment in particular in innovative activities is often unpredictable, meaning that every entrepreneurial decision is risky or even uncertain. Moreover, in contrast to ordinary managers, entrepreneurs often lose their own funds in case of investment failure. Entrepreneurs must, therefore, be willing to bear risks or even uncertainty and have accordingly high risk tolerances.

The second characteristic, openness for experience, describes an individual's ability to seek new experiences and to explore novel ideas. Persons scoring high on openness to experience are typically creative, innovative, and curious. These attributes are particularly crucial for individuals intending to start an innovative new venture, but also for replicative entrepreneurs aiming to create a unique selling proposition in their own firm.

The two further traits relate to another aspect discussed in the previous section, namely the managerial capacities of heading an own company. In this context, *locus of control* measures generalized expectations about internal and external control of reinforcement. People with an internal locus of control believe that they determine their future outcomes through their own actions. Persons with an external locus of control believe that their own future development is determined randomly or by the external environment, but not by their own actions. As entrepreneurs must continuously make decisions related to their business outcomes, a high level of internal locus of control is a relevant personality characteristic for all entrepreneurial decisions. The last trait, *extraversion*, consists of variables that describe the extent that individuals are

assertive, dominant, ambitious, energetic, and seek leadership roles. Moreover, extraverted individuals tend to be sociable, thus enabling them to develop social networks more easily, which may result in stronger partnerships with clients and suppliers. All parts of the factor – being assertive, seeking leadership, and developing networks – are important if an individual aims to become the head of a firm. Recent empirical research finds that individuals with these personality characteristics have a higher probability of becoming entrepreneurs (Caliendo et al., 2014a).

The important point now is that there are some personality constructs that affect entry into entrepreneurship. However, there are different ones – with the exception of locus of control – or different parameter values of the same construct that affect an exit decision from entrepreneurship and thus success or survival in entrepreneurship. More specifically, empirical research reveals that the most important personality characteristics influencing entrepreneurial success are the following four: lower levels of agreeableness, higher levels of need for achievement, higher levels of locus of control (as mentioned before), and rather medium levels of risk attitudes. Individuals scoring high on agreeableness are described as having a forgiving and trusting nature as well as being altruistic and flexible. Therefore, low scores of agreeableness might, in particular, help entrepreneurs survive as such low levels allow them to bargain for their own interest with their partners. Moreover, need for achievement expresses the motivation of entrepreneurs to realize new and better solutions than those given in the actual (market) environment, through their own performance in the market thus making high scores in this personality construct increasing entrepreneurial success (Holmes and Schmitz, 1990). The same holds for locus of control. Last, but not least, the relationship between risk tolerance and the probability of entrepreneurial success is inverse U-shaped and not linear (Caliendo et al., 2010). Entrepreneurs within a medium range of risk tolerance have the lowest exit probabilities. An explanation is that too low risk tolerance leads to low expected returns from low-risk projects and makes entrepreneurship unattractive in comparison to dependent employment, whereas entrepreneurs who are excessively risk tolerant engage in risky projects with higher failure rates. As to demographic characteristics, it can be further observed that the middle-aged and the well educated also have the highest survival probabilities.

In particular, the result on the impact of risk attitudes on entrepreneurial survival shows that stories about entrepreneurs and their willingness to mortgage their home (as mentioned in the introduction) while making high-risk decisions, with the tale ending that the person has become a billionaire, are good for media and may hold for a handful of people, but not for the majority of entrepreneurs, and that this uncontrolled risk-maximization might not be the best role model to follow. Entrepreneurial activities are more often determined to be successful if a reasonable risk assessment has been conducted.

As the decision to become an entrepreneur might also be influenced by public reports, role models are crucial, giving orientation. Bosma et al. (2012) address the occurrence, function, and characteristics of specific role models in entrepreneurship, in both the pre- and post-start-up phases of firms. Results show that role models matter for potential entrepreneurs: Most of the entrepreneurs have a role model in either of the two phases and view them as influential. One-third of the role model users claim that they would not have started their business without the presence of role models. The dominant functions of role models are 'learning by example,' followed by 'learning by support,' 'increasing entrepreneurial self-efficacy,' and 'inspiration or motivation.'

They also show that role models compensate for a lack of entrepreneurial experience. The individuals behind the role models are older and have much larger firms than their followers. However, icons from media reports are rarely actual role models; they rather tend to come from next-door.

Putting the puzzle together, it becomes clear that many different variables influence this kind of lifetime decision to switch from another employment form to entrepreneurship. Some demographic and some personality variables influencing the entry decision into entrepreneurship have been identified, but in particular with respect to personality traits these are different from the ones influencing entrepreneurial success. This also makes clear why we should refrain from trying to describe what the average entrepreneur should look like.

Why Entrepreneurs Are Important for the Economy?

In the last two decades many economies in the developed world have become more entrepreneurial. This transition is fostered by several factors. The costs and benefits of becoming an entrepreneur are affected, among others, by (1) shifts in demand from standardized mass production toward more individual products; (2) increasing importance of knowledge as an input factor for production; (3) new developments in information and communication technologies that facilitate the coordination of different labor divisions, thus allowing for more flexible small-scale production units; and finally (4) increasing globalization and opening new markets with new investment opportunities for a more productive division of innovative labor (Audretsch and Thurik, 2000). Those factors have led to a reduction of the minimum efficient size of production, to lower entry barriers and to new entrepreneurial opportunities.

What kind of effects can economies experience when entrepreneurs do enter markets?

First, and foremost, innovative entrepreneurs may create product or process innovations and open new markets. There are many examples of radical innovations introduced by entrepreneurs who founded firms like eBay, Google, Amazon, Oracle, SAP, Microsoft, Apple, and Skype. The companies emerging out of these innovations often affected economic growth (Valliere and Peterson, 2009). Innovative entrepreneurs thus offer a key value-generating contribution to economic progress. Their pronounced role with their new firms may be driven by the fact that compared with incumbent suppliers, new firms may invest more in searching for new opportunities. Incumbent suppliers are more reluctant to do so, either because of their failure to respond to changes in their environment due to organizational inertia, or because these newly invented goods compete with their established range of products. Therefore, established firms often miss the opportunity to adopt new ideas, and setting up one's own business appears to

be the only way for inventors to commercialize their knowledge (Klepper, 2009).

Job creation by entrepreneurs is another crucial issue. Entrepreneurs and their new firms can stimulate employment growth by generating new jobs. Such evidence is found for OECD economies (Carree and Thurik, 2008). However, when analyzing the employment effect of new firms over time, it is interesting to note that the effect for the economy must not be positive at all times. There is an S-shaped effect (see Fritsch, 2008), with entrepreneurship positive in the start-up phase and in the long run, while in the medium turn a decrease in employment can occur when new businesses fail to compete or crowd out incumbent firms.

Entrepreneurs entering the market with their new firms have several further effects to the economy. New firms increase the competition in the market by their pure number and thus decrease the market power of incumbents. They may also intensify competition between them and existing businesses. As this may push established firms to improve their performance, such kind of increased competition is particularly utility-increasing for consumers who realize lower prices and a greater product variety.

Competition between entrepreneurs and incumbent firms ideally leads to the 'survival of the fittest.' Accordingly, new firms should also foster productivity (see Geroski, 1989). This productivity-enhancing effect of new business formation should become evident shortly after entry because only entrepreneurs who perceive a gap in the market or are more efficient than existent market player will enter the market. Entry and the resulting selection process induce movements of the production frontier with less-efficient firms (both entrants and incumbents) dropping out. Empirical studies show that there is a positive relationship between the level of early-stage entrepreneurial activity and productivity. This relationship is particularly strong for entrepreneurs with high-growth and innovative ambitions while entrepreneurs with low-growth ambitions have a weaker but still positive impact on productivity. This pattern indicates that entrepreneurs generally increase the productive use of scarce resources in an economy with the strongest impact coming from innovative entrepreneurs.

Entrepreneurs may also be able to foster structural change: Incumbent firms often struggle to adjust to new market conditions and permanent changes. Thus failing to make necessary internal changes because they lack the ability for 'creative destruction' (Schumpeter, 1934). The entry of new businesses accompanied by an exit of some incumbents can help to free firms from this 'lock-in' situation. Moreover, they can "initiate the emergence of new markets and industries that may be drivers of growth processes" (Klepper, 2009).

Entrepreneurial Failure and Closure

It is an innate problem of entrepreneurship that during the first 5 years after starting their businesses, entrepreneurs have a substantial risk of failure or closure of their new firms. There are several reasons for failure and closure. First, not every individual is able to become a successful entrepreneur and may not have known prior to starting the business. Further reasons for failure include (1) restricted access to capital; (2) lack of customers; (3) poor managerial skills; and (4) the costs of regulatory burdens. These burdens can, for example, come in the form of lengthy registration procedures and complicated permit or license regulations. Typical failure rates are around 40–50% over the first 5 years of a firm, with the highest failure rate in the first year.

Summary

Entrepreneurs, while rarely existing in highly developed economies, serve several crucial functions in an economy. They create employment opportunities for themselves and others. Entrepreneurial activities may further influence the overall economic performance in a country because entrepreneurs do not just innovate but also influence productivity, competition, and structural change. Therefore, new business formation by entrepreneurs is regarded as a critical source of economic and employment growth.

Research in entrepreneurship is appealing for various reasons: First of all it is about the understanding of a rare species. Second, it combines research from all kinds of areas including economics, psychology, sociology, and management. Research bridging these disciplines improves understanding entrepreneurship and its effects. Third, entrepreneurial activities are particularly dynamic, which is why it is challenging to model these activities. Closing with the words of Barreto (1989: p. 141): "Simply put, entrepreneurship is above 'formalization' – it cannot be neatly packaged within a mechanistic, deterministic model." Future research has, on the one hand, the challenge of developing nonmechanistic models that bridge this gap. On the other hand, we are still far from fully explaining why some entrepreneurs are more successful than others. Finding better answers to the first question might open up new avenues to analyze the second.

Abstract

Entrepreneurship can be broadly defined as the identification and organized exploitation of novel opportunities for value creation and capture, where the value outcomes may be commercial, social, institutional, or cultural in nature. Hence, entrepreneurship has wide relevance for societies and economies. As a field of practice, entrepreneurship has grown continually since its emergence during the industrial revolution of the eighteenth and nineteenth centuries. More recently, entrepreneurship has taken on a wider meaning, as the process or activity whereby new organizational forms are created to exploit value-creating opportunities, even when the resources and capabilities to do so are not yet at hand.

Entrepreneurship can be broadly defined as the identification and organized exploitation of novel opportunities for value creation and capture, where the intended value outcomes may be commercial, social, institutional, or cultural in nature. Hence, entrepreneurship has wide relevance for societies and economies. Indeed, in the early twenty-first century, entrepreneurship is widely viewed as a major source of economic growth, job creation, and innovation. It has become a major topic of interest for governments, companies, educational institutions, and enterprising individuals. In parallel, scholarship on the subject has blossomed as well.

The modern concept of entrepreneurship has historic roots in European history (Hébert and Link, 2009). The origin of the word 'entrepreneur' can be traced to a time of warfare, rather than of economic change, in sixteenth-century France. During this period, entrepreneurs were defined as profit-seeking project workers, master builders, or manufacturers. Often the term referred to government contractors or the builders of military fortifications. Only later, in the eighteenth century, was the concept of entrepreneurship applied to economic actors as we understand them today. From this perspective, an entrepreneur was someone who either undertook contracts for public works, or introduced new agricultural techniques in their land, or risked their own capital in industry. More recently, the concept of entrepreneurship has taken on a wider meaning again, as the process or activity whereby new organizations are created to exploit value-creating opportunities, even when the resources and capabilities to do so are not yet at hand and the risk of failure is high.

Early Scholarship

Early scholarship on the topic of entrepreneurship reflected cultural and intellectual trends in eighteenth- and nineteenth-century Europe. During this period, Enlightenment thought and political revolution advocated cultural change, social mobility, and economic progress, providing entrepreneurial activity with both meaning and vitality. At the same time, early waves of industrialization and associated wealth redistribution were opening up new opportunities for entrepreneurship in the commercial sphere. Not surprisingly, therefore, French Enlightenment scholars such as Cantillon and Turgot advocated entrepreneurial activity. They stressed the need for individuals to accept the risk and uncertainty inherent in economic activity as its key distinctive feature.

During the same period, economic thought also began to incorporate conceptions of entrepreneurship (Hébert and Link, 2009). For example, Jean Baptiste Say defined the entrepreneur as the person who combines the factors of production for profit, putting him or herself at the center of several relations among capitalists, workers, technicians, merchants, and consumers; while the economist and philosopher John Stuart Mill discussed the entrepreneurial function in relation to the provision of risk capital. Later scholars built on these foundational thinkers, and their insights continue to infuse understanding about entrepreneurship.

However, it was not until the late nineteenth and early twentieth centuries that the sociologist Max Weber, and then the economist Joseph Schumpeter, provided deeper theoretical analyses of entrepreneurship as a force within society and the economy. Weber analyzed entrepreneurship in terms of the interplay between the religious mentality of Protestantism and modern rationalism in the rise of capitalism (Weber, 2007). In this context, the entrepreneur is distinguished from historical predecessors in traditional economies by virtue of a rational and systematic pursuit of economic gain and the subordination of consumption in the interest of capital accumulation. For Weber, entrepreneurship was an expression of this modern mentality.

A few decades later, Schumpeter provided one of the first and most thorough analyses of the entrepreneurial function from an economic viewpoint. In his early work, he conceptualized entrepreneurship as a driver of innovation within cycles of industrial change, thus giving it a dynamic quality lacking in earlier formulations (Schumpeter, 1934). Through entrepreneurial action and innovation, he argued, the novel combination of the factors of production, when combined with credit, disrupts the static equilibrium of economic life. Entrepreneurial action therefore changes the conditions of supply, combines existing resources in new ways, and creates new production functions. Waves of creative destruction are then released. For this reason, Schumpeter stressed the revolutionary character of entrepreneurial action.

During the following years of the twentieth century, the pace of global economic change quickened. In fact, on many dimensions – social, political, technological as well as economic – the pace of change during this period was as great as any time in human history. Rapid change continues in the early decades of the twenty-first century, breeding risk and opportunity. Reflecting these trends, entrepreneurship has become more prevalent and encouraged. Indeed, entrepreneurship is now widely promoted as an important factor in achieving economic growth and social development.

The Field of Entrepreneurship

Reflecting the social and economic trends of the late twentieth and early twenty-first centuries, entrepreneurship has emerged as a significant area of scholarly research, management practice, and government policy. Indeed, like many areas of scholarship about organizations and management, research into entrepreneurship has mushroomed during this period, resulting in a variety of perspectives. Chief among them are process theories, sociological, psychological and economic perspectives, and practice-oriented approaches. Following sections discuss each in turn.

It is important to note, however, that the status of entrepreneurship as an autonomous field of academic study remains controversial. On the one hand, some scholars argue that entrepreneurship as an area of study is correctly defined in terms of the phenomena it encompasses, rather than distinctive theories (e.g., Sorenson and Stuart, 2008). Relevant phenomena of interest include new ventures, investor networks, innovative business models, and the characteristics of the founders of new ventures. Advocates of this view do not regard entrepreneurship as a separate field of study, defined in terms of a distinct body of supporting theory. They argue instead that research into entrepreneurship must borrow from other disciplines and fields of study for explanatory theories and frameworks. Adopting this perspective, the study of entrepreneurship is distinguished by its phenomenal qualities.

On the other hand, an equally rigorous community of scholars does accord entrepreneurship the status of a distinct field of study (e.g., Busenitz et al., 2003; Shane, 2003). They argue that the processes and behaviors of entrepreneurship have special features which call for unique and specialized theories, above and beyond potential borrowings from other disciplines. From this perspective, any attempt fully to explain the phenomenal richness of entrepreneurship, embracing process, people, and profit, demands a form of synthesis that is not found in other fields. At the time of writing, this debate continues. It evidences the enduring complexity and breadth of entrepreneurship as both a phenomenon and topic of research.

Process Theories

The process of new venture creation is often seen as the archetype of entrepreneurial activity. In summary, an entrepreneur senses a market opportunity, creates a new organization, builds a team, and gathers the resources required to exploit the opportunity, perhaps raising venture capital investment, and then seeks to grow the business. This process perspective was clearly articulated by Shane and Venkataraman (2000) in a highly influential paper. They explained that entrepreneurship should be conceived as "the nexus of two phenomena: the presence of lucrative opportunities and the presence of enterprising individuals" (Shane and Venkataraman, 2000: 218). Following their advice, many scholars research the interaction of opportunities and individuals in the entrepreneurial process. Important phases of the process include opportunity recognition or creation, venture founding, team building, and resource accumulation.

Not all scholars agree, however, regarding the nature of the entrepreneurial process and its core phases. One major debate focuses on whether new opportunities exist objectively, and thus wait to be discovered; or whether opportunities come into being through entrepreneurial imagination and action (Alvarez and Barney, 2010). In other words, are opportunities discovered or created? In fact, there is evidence to suggest that opportunities may emerge via both routes. Sometimes, the market or social context exhibits clear needs that await entrepreneurial attention, while in other contexts, it requires original insight, imagination, and action to create and shape opportunities.

Another debate focuses on the role of the individual entrepreneur in the entrepreneurial process. Schumpeter exemplified the debate. In his early work, he emphasized the role of the individual entrepreneur in economic change. In his later work, however, he argued that industrial and economic forces were more important in the explanation of entrepreneurial activity. For the late Schumpeter, markets matter most, and while entrepreneurs play an important role, they are more the mediators than originators of entrepreneurial processes. Other scholars take the opposite view, and argue that founders are critical to the entrepreneurial process (Wasserman, 2012). They maintain that individual entrepreneurs create opportunities, found new ventures, and initiate industrial change. This debate also relates to the sociological and psychological perspectives on entrepreneurship, which are discussed in the next section.

Process theories also imply logics of progression across phases of stages of activity. Once again, approaches vary. Some argue it is possible to conceive of and explain cause and effect in the entrepreneurial process. For example, assuming causal relationships, entrepreneurs choose to pursue opportunities, build plans, and then create new ventures and act deliberately in the exploitation of their chosen opportunity. In contrast, Sarasvathy (2001) argues that causal explanations are not feasible in the uncertain, unpredictable realm of entrepreneurship. Following the general argument espoused by the economist Frank Knight (1942), Sarasvathy proposes that entrepreneurs effect the future, rather than cause it. In her 'effectuation theory,' one starts with only a set of means; in the process of deploying these means, goals gradually emerge. Using an effectual logic, future outcomes are not the result of causation, but rather emerge unpredictably from meaningful action. Indeed, most scholars agree that entrepreneurship involves high risk and uncertainty. The degree to which these conditions can be subject to causal or effectual reasoning may depend largely on the relative degrees of uncertainty in any given opportunity context.

Psychological and Sociological Approaches

Irrespective of the process logic one employs, entrepreneurship is clearly related to human thought and action, at both the individual and collective levels. Founders create firms and build teams, and these teams work together under pressure and uncertainty to pursue shared goals. They use networks and social relationships to gather resources and leverage influence. Hence, social, individual, and group factors play important roles. Many scholars therefore employ psychological and sociological theories and techniques to understand entrepreneurship.

From a psychological perspective, researchers employ numerous theories, including theories of personality, motivation, goal setting, decision making, perception, and self-regulation; and from the sociological perspective, theories of organizational populations, institutional legitimacy, organizational imprinting, and embeddedness. Major research questions in the psychological stream of research include the following: Why do some people choose entrepreneurship while others do not? Are entrepreneurs more alert to opportunities, and if so why? What are the characteristics or traits which drive some individuals to persist in the face of uncertainty and possible failure? and Are entrepreneurs more or less aware and tolerant of risk, when compared to non-entrepreneurs? (Baron, 2004). From a sociological perspective, typical research questions are the following: To what degree are new ventures reflective of their surrounding organizational context? How do new organizations emerge and evolve over time, and gain legitimacy? How do the early culture and routines of an entrepreneurial firm become imprinted and enduring as the organization grows, and with what effects? (Johnson, 2007).

Over two decades of research since the 1990s, many studies have investigated these and related questions, hoping to uncover the factors which help to explain and predict entrepreneurship (Grégoire et al., 2011; Sorenson and Stuart, 2008). However, the results have been mixed. To begin with, from the psychological perspective, personality trait theories are now broadly rejected; that is, few believe that entrepreneurs possess specific and distinctive personality traits. However, cognitive studies continue to be enlightening. There is good evidence that entrepreneurs think differently about risk, decision making, experimenting, planning, and goal setting (Bryant, 2007). They also appear to be more alert to opportunities, based on cognitive skills of pattern recognition and creativity (Baron, 2006). Evidence also suggests that such cognitive skills can be learned and enhanced over time.

Furthermore, in recent years, scholars have started to investigate entrepreneurial cognition using the tools and techniques of cognitive neuroscience. They hope to identify whether and how entrepreneurial thought and action are associated with individuals' neurophysiological characteristics (e.g., Laureiro-Martínez et al., 2010). While this research program is in its infancy, one can expect significant findings in future years, adding to the cognitive and psychological perspectives on the subject.

From a sociological perspective, research has shown that social networks, social capital, and integration into social structures are important for entrepreneurship (Busenitz et al., 2003). For example, social connections often help founders to attract talent and resources to new ventures. Social networks can open doors to opportunities and markets, and can be especially significant as sources of information and strategic intelligence. Indeed, from a social network perspective, entrepreneurship can be conceived as a boundary spanning or brokerage activity, whereby entrepreneurs link people, information, and resources across preexisting social and organizational boundaries (Burt, 2004). Studies also show that membership of social networks enhances status and trust in attracting investment and collaborators. For new ventures, such benefits are significant, given their liabilities of newness.

At another level of social organization, entrepreneurs are institutional actors. They hold governance roles in new organizations, influence the emergence of organizational cultures and behavioral norms, and imprint foundational norms and routines. Indeed, many entrepreneurs actively create new institutions and organizational forms, sometimes through leading the evolution of new social movements in response to unmet social needs or perceived injustice. Hence scholars investigate how institutional factors – such as culture, social norms, behavioral routines, and organizational structures – contribute to our understanding of entrepreneurship (Battilana et al., 2009). Moreover, as new organizational forms and social movements continue to emerge, institutional entrepreneurship may become even more salient in future years.

Economic Perspectives

Another rich tradition of research into entrepreneurship focuses on economic factors. As noted earlier, writing from within the Austrian tradition of economic thought, Schumpeter was the foundational theorist in modern times. He conceived of entrepreneurship as an important and inherent feature of economic change and development. More recently, Israel Kirzner (1998) has developed an influential theory of entrepreneurship, also based in the Austrian economic tradition. He emphasizes the role of entrepreneurial discovery and alertness to opportunities as key elements in the dynamics of nonequilibrium markets. In doing so, Kirzner reinvigorated interest in Schumpeter as well, by connecting the Austrian economic tradition to more contemporary microeconomic debates.

Working in a similar vein, evolutionary economists such as Nelson and Winter (1982) propose a sophisticated evolutionary theory of economic change which draws heavily on Schumpeter's ideas about innovation and industrial dynamics. Contrary to classical economic theories which assume utility maximization in near equilibrium states, Nelson and Winter argue that economies are in a continual state of evolutionary adaptation, driven by 'Schumpeterian competition' and supported by new combinations of routines at the firm level. In a subsequent paper, Winter (2006) continued this line of research by proposing a neo-Schumpeterian theory of the firm in which entrepreneurs play a central role as the leaders of new techniques and resource combinations. From this perspective, entrepreneurial action is central to the evolution of economic systems, the emergence of firms, and broader patterns of innovation. Assuming this perspective, entrepreneurship is best

understood in the context of industrial dynamics and economic change.

As Schumpeter also noted, technological innovation is a particularly important stimulus of economic change and entrepreneurship. Recent examples are compelling: companies such as Microsoft, Google, Apple, Genentech (all founded in the USA), Infosys (in India), Alibaba (in the People's Republic of China), and Samsung (in South Korea). In the early years of the twenty-first century, all are successful global companies that began as entrepreneurial ventures seeking to exploit opportunities based in innovative technologies. Indeed, technological innovation is now viewed as a major driver of entrepreneurship with its own principles of practice (Hsu et al., 2007). The 'Lean Startup' approach to new venture creation is a good example of this trend (Blank, 2013). In contrast to traditional theories of entrepreneurial ventures, the Lean approach advocates continual customer discovery, the rapid prototyping of minimum viable products, readiness to fail, and the necessity for adaptation or pivoting. It is especially applicable in the dynamic context of Internet-based entrepreneurship, but elements of the method are applied more widely as well.

Entrepreneurial Practice

Entrepreneurship is also an increasingly important area of management practice. Even in large established organizations, employee entrepreneurs (sometimes referred to as 'intrapreneurs') help to develop new business opportunities, open new markets, and foster organizational innovation. This significant area of practice has spawned a growing literature on corporate entrepreneurship and spinoff companies (e.g., Shepherd et al., 2009). Indeed, many established organizations now actively seek to encourage entrepreneurial activity by their employees, as a way to grow and adapt in an increasingly uncertain world. David Teece (2007) captures this trend in his theory about the dynamic capabilities which firms need in order to reconfigure their resources and activities in response to opportunities. From this perspective, even large companies must develop entrepreneurial capabilities and characteristics in order to compete in a dynamic world. In summary, entrepreneurship is not only about new startup ventures.

Social change agents can also be described in terms of entrepreneurship. For example, the founder of the Grameen Bank of Bangladesh, Dr Muhammad Yunus, was awarded the Nobel Peace Prize in 2006 for his entrepreneurship in the social sector. Imitating his ground breaking work, microfinance has emerged as a global industry, offering small affordable loans to people in the lowest income brackets. Comparable innovations can be observed in other areas of social life. In fact, many governments now look to social entrepreneurship and social businesses to help address many of the needs and opportunities in areas of social life, such as health, education, and environmental sustainability. As a consequence, in the early twenty-first century, social entrepreneurship and its close variant social business have become very significant areas of research and practice (Dees, 2007). Founders of this type of venture aim to solve pressing social challenges, and they often see opportunities in areas where the state has been inadequate or failed to act. Importantly, and in contrast to commercially driven entrepreneurship, social entrepreneurs hope to create value that members of society will capture and enjoy, rather than capturing the value for themselves as profits. These novel patterns of entrepreneurship also challenge the adequacy of purely economic accounts, because the goals of such activity are often more social than economic.

These developments pose a number of deep questions for scholars, policy makers, and practitioners. On the one hand, dynamic change and social challenges are stimulating more entrepreneurial action in a wide range of commercial, social, and institutional fields; especially as governments and social institutions often fail to respond to problems in a timely and effective manner. On the other hand, entrepreneurs as a group of actors are unlikely to fill the apparent void created by incapable or ineffective institutions – and scaling effective solutions is always difficult. The question then arises: How can and should social and political institutions nurture the entrepreneurial capabilities required to address the challenges and opportunities of the contemporary world? And what does this question imply for the future of public institutions and good governance? Such questions are already topics of study and no doubt will continue to attract significant attention (Christensen et al., 2006).

Global Trends

Ongoing globalization is having an equally profound impact on entrepreneurship. Across the developing world especially, rates of entrepreneurial activity and economic growth are unprecedented. Countries such as China, India, and Brazil are following the example set by other Asian economies in the late twentieth century (Mathews, 2006). Within a few decades, these nations have grown their economies and command an increasing share of global trade and wealth. Entrepreneurship has been critical to this success. The question is therefore posed, whether a new variant of entrepreneurship is emerging, or will developing economies exhibit the same entrepreneurial processes observed in older developed economies? A number of factors suggest there may be significant differences compared to the role of entrepreneurship in earlier phases of industrial change: in many rapidly emerging economies, government agencies are playing a more important role; imitative strategies are common, as opposed to more disruptive innovations; entrepreneurial action is also growing among the poorest members of society – at the so-called 'bottom of the pyramid' (Prahalad, 2005) – although wider social and political changes have not always been commensurate.

Entrepreneurship is also gaining increasing attention in relation to international business, competitive strategy, marketing, and other fields of management and organizational research. For example, in 2009 the prestigious Strategic Management Society founded a dedicated journal for such research titled the "Strategic Entrepreneurship Journal." Indeed, noting the dynamic nature of markets and industries in the early twenty-first century, some now argue that competitive strategy and entrepreneurship are deeply integrated and almost synonymous (Spender, 2014).

Conclusion

As markets, societies, and technologies continue to change, adapt, and transform, there will be a constant flow of opportunities to create and capture value in new and innovative ways. Moreover, these developments are globally pervasive, and entrepreneurship will be deeply relevant for organized responses to such change. We can therefore predict that entrepreneurship will continue to flourish, as both an area of research and a domain of practice.

Abstract

The study of entrepreneurship plays a central role in understanding the changing geography of the economy. Entrepreneurship is a process that involves the creation and growth of new companies. There is a well-developed literature on entrepreneurship and agglomerations or clusters and also ethnic entrepreneurship. Further research is urgently required to understand the emergence of 'born global firms' or companies that from their initial moment of inception seek to develop an international or global presence.

The study of entrepreneurship plays a central role in understanding the changing geography of the economy (de Groot et al., 2004; Scott, 2006; Stam, 2007). Entrepreneurship is a process or activity that involves the creation and growth of new companies. This process includes the identification of opportunities to supply new goods and services and to organize factor inputs in new ways (Bryson et al., 1993). Entrepreneurship includes developing products and services that may be new to the market or creating new firms that are intended to supply services and goods that already exist. This definition implies that the academic study of entrepreneurship includes a focus on understanding why, when, how, and where entrepreneurship occurs. It must also include a focus on the role gender (Hanson, 2009; Hanson and Blake, 2009), ethnicity, and age play in entrepreneurship. Two elements are central to this definition. First, an emphasis on self-employment in which an individual or group of individuals creates the conditions for their own employment. This is to highlight that entrepreneurship is about engaging in work for personal profit rather than salaried employment. Second, is an emphasis on understanding the processes and practices that result in the establishment of a new enterprise.

The on-going complexity of the division of labor continues to create new business and employment opportunities as often novel ways of dividing tasks are identified. This has led to the emergence of many new types of self-employment including personal trainers, image consultants, dog walkers, and life-style coaches. There are many different types of self-employment or entrepreneurship. This includes 'part-time' self-employment that may be facilitated by full-time employment or self-employment intended to provide flexibility to support caring for dependents. The former includes eBay entrepreneurs who buy and sell on the Web site either as a hobby or as a full-time business. Social entrepreneurs are a distinct type of entrepreneur who are interested in creating products or services to solve social needs and problems.

The development of the World Wide Web (WWW), e-commerce, and networked economies has greatly enhanced the ability of individuals to become entrepreneurs (Nijkamp, 2003). The WWW enables a spare bedroom to be converted into an online shop, but also facilitates the sourcing of goods from companies connected to WWW. This explains the growth in virtual manufacturing firms – firms that design and market manufactured goods but outsource the fabrication process to contract manufacturers. Selling customized products has become much easier as has identifying potential low-cost manufacturers. Innovations in manufacturing technology are also creating new business opportunities. Developments in 3D printing, additive manufacturing, or digital fabrication are enabling individuals to establish craft-based enterprises that have the ability to 3D print-customized products or to design products and outsource the 3D printing process to a specialist supplier. Technological innovations have led to the development of many new opportunities for entrepreneurial behavior using innovative business models with new geographies.

The academic literature on entrepreneurship has emphasized understanding the causes of entrepreneurship and its effects but has had limited success in explaining entrepreneurial behavior. In a small enterprise, the owner-manager plays four distinct roles: financier; orchestrator of capital, raw materials, labor, and financial and management information; innovator constantly searching for ways to improve output and productivity; and finally "a creator of jobs and a member and stimulator in the local and regional milieu" (Marchesnay and Julien, 1990: 269). Marchesnay and Julien suggest that it is unusual to find an entrepreneur who possesses all four characteristics, and more importantly, it is likely that an opposition exists between the "roles of discoverer, innovator, 'adventurer' or 'gambler' and those of organiser, manager and accountant" (1990: 269). The establishment of a new company, or the management of an existing small firm, requires a solution to what Baker and Faulkner have termed a 'combinational problem' (1991: 283). In their study of the Hollywood film industry, they describe the ways in which changing combinations of technical, capital, management, and support services are required at different stages in the evolution of an organization (Kenny and Patton, 2005). The combinational problem explains the existence of serial entrepreneurship; entrepreneurs who continually establish new firms and sell them or transfer the day-to-day management to someone else. Serial entrepreneurs have a special ability to identify gaps in a market, but may not have the skills or interest required to manage a business over a long time period.

Joseph A. Schumpeter was one of the most important social scientists to work on entrepreneurship. The entrepreneur plays a central role in all Schumpeter's writings (1947) with a particular emphasis on the relationship between innovation,

entrepreneurship, and creative destruction. Schumpeter was an economist who reclaimed the concept of the entrepreneur for economics by incorporating social and cultural approaches into his theory of entrepreneurship (Schumpeter, 1947). This theory defines the entrepreneurial process as one that involves the assemblage of new combinations of existing resources or assets. Entrepreneurs create new rules that have the potential to destroy existing processes and products as part of a process of creative destruction. Prior to Schumpeter, the cultural and social aspects of entrepreneurship had been neglected by economists. Nevertheless, Schumpeter was unable to persuade economists to develop a sociologically nuanced account of entrepreneurship as "economists are prone to treat as nonexistent what is not quantifiable and sometimes even what is not measureable" (Schumpeter, 1947: 149–159). It was geographers and sociologists who eventually made an important contribution to understanding the social and cultural aspects of entrepreneurship.

The study of entrepreneurship has become a central focus of the social sciences and has led to the emergence of a specialist academic subdiscipline that focuses on entrepreneurship. Much of this debate has been located in business schools, but geographers have also made important contributions to understanding the complex and evolving geographies of entrepreneurship (Bryson et al., 1993). The geographical debates on entrepreneurship have focused on understanding entrepreneurship and place (Parthasarathy and Aoyama, 2006; Aoyama, 2009; Reuschke, and Van Harn, 2013), new industrial districts or clustering (Scott, 1988), high-technology firms (Saxenian, 1994), entrepreneurship and services (Wood, 1991), ethnic entrepreneurship (Ram et al., 2002; Harris et al., 2012), and business support (Bryson and Daniels, 1998). It is worth noting that the study of the geography of entrepreneurship has never been a core research area in economic geography; at best it has been marginal. The *Oxford Handbook of Economic Geography*, for example, has only two entries in its subject index that refer to entrepreneurship – entrepreneurship and culture and entrepreneurship and location (Clark et al., 2000). The topic of entrepreneurship is present, but hidden in accounts of agglomeration and clustering. Entrepreneurship is a core part of geography, but the term and the literature of entrepreneurship has been largely sidelined within economic geography. Economic geographers have made many contributions to understanding firm behavior, firm formation, entrepreneurship, and cultural diversity (Nathan and Lee, 2013) and agglomeration or clusters (Delgado et al., 2010), but have tended not to frame their analysis within accounts of entrepreneurship. In this context, it is possible to argue that the geography of entrepreneurship is underdeveloped and still awaits the type of attention that has been placed on understanding the evolving geographies of global business (Dicken, 2003).

Entrepreneurship: From Fordism to Post-Fordism

The academic study of entrepreneurship emerged during the early years of the nineteenth century. During the late 1970s and early 1980s, entrepreneurial studies developed as a core focus of academics interested in business and management and of social scientists interested in understanding the geography or sociology of economic activity. Within the business school community, new chairs in entrepreneurship were established and a number of important new academic journals were established including *Frontiers in Entrepreneurship* (1981–Till present), *International Small Business Journal* (1982), *Journal of Business Venturing* (1985–Till present), *Small Business Economics* (1989–Till present), *Entrepreneurship and Regional Development* (1989–Till present), and the *International Journal of Entrepreneurship and Small Business* (2004).

The late 1960s and 1970s had seen a focus on understanding the developing geographies of large transnational corporations (TNCs) and the relative neglect of smaller firms. The post-1960s economy was going to be dominated by the activities of large TNCs and smaller firms were regarded as being of secondary or of only local importance. The period from the late-1970s heralded the rediscovery of the role small- and medium-sized enterprises (SMEs) played in national economies. This rediscovery of the importance of SMEs was partly based on an upsurge in the formation of new firms, but also a new policy interest in understanding SMEs as a possible solution to unemployment. In July 1969, the UK government established the *Committee of Inquiry on Small Firms*, which published the Bolton Report in 1971. Since the publication of the Bolton Report successive governments have introduced policies designed to encourage new firm formation and small firm growth (Bolton Report, 1971). The new emphasis placed by governments on entrepreneurship led to a revival in the academic study of small firms and the emergence of entrepreneurship as an academic subdiscipline. Within geography the new interest in small firms was reflected in a shift from studies that focused on the developing geographies of the Fordist regime of accumulation with a focus on large firms to a new focus on post-Fordism and an appreciation of the role SMEs played in flexible production systems. Within geography, the conceptual framework developed by French regulation theory was extremely influential in shifting the focus of research toward understanding the geography of smaller firms (Tickell and Peck, 1992).

Fordism was identified as a regime of accumulation based on mass production and consumption and the emergence of large firms. Wages were set by collective bargaining and a substantial proportion of employment was in manufacturing firms. Post-Fordism was a result of a crisis in Fordism that emerged in the early 1970s. A new regime of post-Fordism was identified based on flexible, specialized production. This included a revival in the role of SMEs and localized or clustered value chains (Wood, 1991). The identification of a shift from Fordism to post-Fordism highlighted the major transformations that were underway in the economies and societies of developed market economies. Nevertheless, the distinction also had its problems. The social sciences translated Henry Ford into Fordism and Frederick Taylor into Taylorism. These two individuals are identified with processes that are considered by many social scientists to have been critical in the evolution of advanced capitalism (Williams et al., 1992). Fordism became such a key concept that post-Fordism and neo-Fordism were developed as terms to define production systems that developed after the crisis of Fordism, identified as having occurred in the 1970s.

New Industrial Districts and Entrepreneurship

The shift in research emphasis toward post-Fordism was associated with a growth in research that explored the functioning of industrial districts or clusters (Scott, 1988). It is worth noting that economic geographers during the late 1960s and early 1970s focused on understanding the importance of 'industrial linkage.' This early literature reflects geographers' long-term interest in the spatial aspects of interfirm relationships. Industrial linkage is defined "as occurring when one manufacturing firm purchases inputs of goods and services from, or sells outputs to, another manufacturing firm" (Keeble, 1976: 61). Initially studies emphasized localized linkages, but "linkages can and do occur over considerable distances" (Keeble, 1976: 61). Industrial linkage is explained by the operation of a division of labor with firms specializing to minimize total production costs and to enhance profitability. The industrial linkage literature did include studies of industrial districts that explored "sharply demarcated 'swarms' of small firms in particular industries" (Keeble, 1976: 62) and perhaps the most famous study is Wise's analysis of the Birmingham jewelry and gun quarters (1949). An industrial district consists of a territorial system of SMEs. Industrial district studies shifted the research focus away from understanding the activities of single firms to understanding the social characteristics and functions of colocated firms. The research identified distinct agglomerations of firms that specialized in the creation of particular products. A central element of this research was a focus on embeddedness as a key analytical construct (Granovetter, 1985). This approach emphasized the embedding of business activities within much deeper and complex social processes. Much of this literature stressed the importance of localized learning and the transfer of forms of tacit rather than codified knowledge between individuals (Maskell and Malmberg, 1999). Codified knowledge could be relatively easily transferred between individuals and firms, but tacit knowledge could only be transferred through everyday practice and required various forms of face-to-face interaction. This literature also highlighted the relationship between place and entrepreneurship with a focus on cultural, social, economic, and political differences. There are thus important differences between places in terms of the emphasis different cultures place on entrepreneurship as well as differences in the type and availability of factor inputs (Aoyama, 2009; Barbu et al., 2013). Differences in factor inputs include access to finance, business support, and taxation systems intended to encourage entrepreneurial behavior (Scott, 2006).

The geographical literature on clustering is extensive (Scott, 1988; Taylor, 2010). Much of this research focused on what were identified as the three most important regions of the Third Italy: Veneto, Emila-Romagna, and Tuscany (Brusco, 1986). Industrial districts consist of two related processes. One set of processes reflects the functional characteristics of external economies. These include an extensive division of labor between colocated firms that reflect close intra- and intersectoral input–output relationships. Distinct product specialization at the level of the enterprise enables firms to work together as part of a localized value chain. Second, a local concentration includes a territorial- or place-based dimension. This includes local concentrations of skilled labor and of networks and local structures that facilitate local learning. These two processes also contribute to new firm formation or entrepreneurship. The existence of networks that facilitate localized learning and access to skilled labor as well as raw materials encourage new firms to be established. An industrial district is continually reinforced through the establishment of new firms. Employees working for firms within the district are able to access the resources required to establish their own companies. Such resources include access to localized learning, raw materials, suppliers, and potential customers. This implies that it may be easier to establish a new firm within a cluster. The density of small- and medium-sized firms in a cluster will reflect on-going processes of entrepreneurship and new firm formation. This means that the geographical literature on industrial districts or clusters is also a literature on entrepreneurship (Wood, 2004; Delgado et al., 2010).

Some industrial sectors have a greater propensity to form company spin-offs or new firms. An important enabler of new firm formation is the existence of limited barriers to firm formation. These barriers usually consist of access to capital required to purchase or lease land, machines, and raw materials and to cover the expenses related to firm formation. Establishing a service firm is much easier than establishing a capital-intensive manufacturing company. Many knowledge-based business and professional service firms require expertise and a reputation, but, in many instances, limited up-front capital investment.

Social science and economic geography is awash with networks. The 'network turn' in the social sciences has multiple origins. One root lies in actor-network theory (Law, 1999), and other roots are found in accounts of entrepreneurship and social networks (Emirbayer and Goodwin, 1994; Aldrich, 2004). The term 'network' had been transformed in to the dominant collective noun that is used to describe a collection of interactions that occur between organizations, firms, companies, enterprises, and people. Networks play an important role in the literature on agglomeration, entrepreneurship, and localized learning; networks constitute another conceptual framework that geographers have used to explore space, place, and entrepreneurial activity (Bryson et al., 1993).

Clusters have become an important element in many regional economic development strategies but regional strategies overemphasize the importance of clusters at the expense of other forms of policy intervention. Recently, Taylor (2010) has provided an important critique of both the academic and policy literature on clusters. In this critique, he highlights the dangers of adopting cluster development policies without understanding the complexity and diversity that exist within a local or regional economy.

Ethnic Entrepreneurship and Translocal or Transnational Relationships

Minority ethnic entrepreneurship is a major theme within the entrepreneurship literature. Within the UK, this focus can be traced back to Rex and Moore's (1967) classic account of racial conflict in Sparkbrook, Birmingham. Rex and Moore argue that urban society should be conceptualized as consisting of "a number of overlapping and sometimes contradictory systems

of social relations" (1967: 13). This type of analysis is echoed in Albrow's (1997) analysis of old established local people and an Asian community that both live in Tooting, an area in inner London. He argues that "these people inhabit co-existing social spheres, coeval and overlapping in space, but with fundamentally different horizons and time-spans. The reality of Tooting is constituted by the intermeshing and interrelating of these spheres" (Albrow, 1997: 47). These accounts of places that contain distinct and unrelated communities highlight both tensions that can exist between different communities as well as the advantages that can be associated with multiculturalism. Chan (2006) in an interesting account of multiculturalism in Birmingham, UK, based on the analysis of newspapers reveals the ways in which Birmingham City Council has 'rescripted' the character of Birmingham's population as an asset and opportunity rather than a problem or a threat. Part of this rescripting is based around the perceived importance of ethnic entrepreneurs as potential contributors to Birmingham's regeneration through their ability to compete by drawing upon their position in transnational networks. Chan argues that "the ethnic entrepreneur has become analogous with contributions garnered across international borders" (2006: 85) and that this type of activity while being undertheorized by academics had been identified in newspaper articles published in 1990.

Ethnic entrepreneurs provide places with new opportunities to exploit transnational networks. Ethnic entrepreneurs tend to concentrate their activities in sectors, such as catering, with low-entry barriers (Ram et al., 2002). Many of the sectors that ethnic entrepreneurs target suffer from intense competition and 'saturation.' A study of South Asian restaurants in Birmingham noted that this sector had reached saturation so that "any additional supplier renders the market unsustainable at existing levels of consumer demand" and that excessive competition existed (Ram et al., 2002: 27). Minority ethnic entrepreneurs enable places to experience 'globalization from below' – translocal relationships that link migrant communities with their ethnic homeland. This conceptualization of globalization as a process that can be facilitated from below though the articulation of ethnic networks is a well-established aspect of the literature on ethnic enterprise. Ethnic communities located in Western cities can produce ethnic products that are exported to ethnic communities located elsewhere. Thus, Rezaei, though an analysis of the Persian carpet industry, argues that "the formation of immigrant business networks across countries can be understood as a bottom-up globalisation process which complements the standard large firms/top-down one."

Business and professional services (BPS) that provide intermediate inputs to clients can function to connect different parts of the world together (Bryson et al., 1993). An excellent example of transnational BPS that link places is found in Zhou's (1998) analysis of Chinese-owned BPS firms based in Los Angeles. Zhou argues that small, privately owned, and decentralized Chinese accountants, banks, and computer companies located in Los Angeles play a key role in connecting immigrant economic activities with the international circulation of information, goods and capital and especially with their place of origin. In essence, these companies appear to act as enabling mechanisms that ease the expansion of Chinese-based client companies in particular localities in the United States. Since the 1970s, the number of Chinese immigrants and investments has grown rapidly in Los Angeles and it would appear that this growth is self-supporting. The driver behind this process is the operation of ethnic networks that extend access, and provide a mechanism for, regulating and coordinating long-distance interaction. The existing Los Angeles Chinese community utilizes its social relationships with Chinese-based enterprises and acts as an important bridge between Chinese and American business cultures and knowledge. Mitchell and Olds (2000) make the same point in a study of the investment and management practices of Hong Kong property tycoons in Vancouver; Chinese actors link both sides of the Pacific through blending knowledge and business practices. They argue that such knowledge sharing is more flexible than in non-Chinese business firms, and that the flexibility of Chinese firms may be a competitive advantage.

It is important not to 'other' minority ethnic entrepreneurs by suggesting that their business activities are in some way different to other members of a society or to other entrepreneurs. This is an important point in that it is important not to overstate the contribution ethnicity makes to the ways in which enterprises are established and managed (Ram et al., 2002). Much research on ethnic enterprise is constructed around notions of social capital, networks, and communal-familial solidarity as a competitive resource. Emphasizing cultural values in understanding ethnic enterprise is perhaps the oldest conceptual framework that has been applied to understanding ethnic business in the UK (Barrett et al., 2003: 112); this cultural approach tends to focus on relationships within the ethnic group and as such overlooks external relationships with customers and markets. An overemphasis on cultural attributes draws attention away from the institutional and market contexts within which all firms have to operate. Similarly, Ram et al. (2002: 22) note that this type of endogenous approach to ethnic enterprise neglects the role of urban context. Barrett et al. (2003: 133) observe that the cultural approach refuses to die and that "it has resurfaced in that part of human geography which has taken the 'cultural turn.'" Studies based upon "ethnic specificity culturalism may, at times, risk inadvertently promoting a form of stereotyping by highlighting inter-group cultural difference as an explanation of entrepreneurial performance" (Barrett et al., 2003: 113). It is important not to ignore the ethnic embeddedness perspective, but following Barrett et al. (2003) and Ram et al. (2002) the starting point for an analysis of ethnic entrepreneurship must be the analysis of a set of exogenous factors that are found within the local economic, social, and political systems.

Entrepreneurship and Born Global Firms – A New Research Agenda

Economic geography has yet to develop a major research or teaching agenda on entrepreneurship. A reading of the existing geographical literature on entrepreneurship leads to the assumption that entrepreneurship is about clustering or perhaps minority ethnic populations. More recently, an interesting geographical literature is developing on the relationship between place and entrepreneurship and with a particular focus on self-employment (Reuschke and Van Harn, 2013). The

WWW, new technologies and the on-going division of labor have created opportunities for new forms of entrepreneurship. This has created new business models with distinctive and often unusual economic geographies. The study of small firms and entrepreneurship has tended to be relegated to be of secondary importance compared to research into global value chains, TNCs, and international business. Nevertheless, entrepreneurship is a fundamental geographical process, which is both enabled and constrained by place-based relationships and translocal relationships (Yeung, 2009, 2010). There is an interesting opportunity for economic geography to pay more attention to entrepreneurs and entrepreneurship; the study of all types of entrepreneurship and entrepreneurial behavior should form one of the central research and teaching pillars of economic geography.

The world of the entrepreneur is being transformed with technological developments and the emergence of new business models. Developments in e-commerce have reduced firm formation barriers; new firms may be established in unusual locations as long as they have an effective Web presence. The rise of Web-based businesses has led to a major revolution in the geography of entrepreneurship. Nevertheless, this is a revolution that has yet to be explored by geographers but exploratory research has been undertaken in marketing studies (Chetty and Campbell-Hunt, 2004; Hashai, 2011). Conventional approaches to new firm formation highlight that firms are initially established to provide goods and services to local markets. Over time, a firm may begin to trade beyond its local market and eventually may begin to export goods or services. Over the last decade, new firms have been established, which have been 'born global.' A born global firm is a business that from its initial moment of inception seeks to develop an international or global presence. The born global firm begins with a 'borderless' view of the world economy and the formation process includes a strategy to target clients or customers located in other countries. The emergence of born global firms represents an important opportunity to understand the complex ways in which individuals and groups of individuals are developing novel business models that operate at the interface between a set of local and global processes.

This article is a revision of the previous edition article by S.E. Van Der Leeuw, volume 7, pp. 4585–4589, © 2001, Elsevier Ltd.

Abstract

Environmental archaeology, a subdiscipline of archaeology, is defined as the study of the environment and its relationship with people through time. To elucidate this definition, the article summarizes the historical development of the subject, and explores the main subfields of environmental archaeology, namely *geoarchaeology*, *zooarchaeology*, *archaeobotany*, and *geochronology*, with reference to specific case studies. The article also highlights some of the main research themes in environmental archaeology.

Introduction

Environmental archaeology has developed into a major subdiscipline of archaeology over the past five decades, and has attracted scientists from many different backgrounds of academia, including geography, geology, botany, zoology, physics, chemistry, and of course archaeology and anthropology, as well as providing specialist undergraduate and postgraduate training at universities throughout the world. We can define 'environmental archaeology' in archaeology, therefore, as the study of the environment and its relationship with people through time (see Branch et al., 2005); this has in turn led to the development of distinctive subdivisions of environmental archaeology called *geoarchaeology*, *zooarchaeology*, *archaeobotany*, and *geochronology* (see below).

History

During the eighteenth and nineteenth centuries, geologists, such as Lyell (1797–1875) and Hutton (1726–97), by examining the principles of uniformitarianism and laws of stratigraphy, and biologists, such as Darwin (1809–82), by contributing to evolutionary theory, laid the foundations of environmental archaeology. Uniformitarianism, in particular, is a key scientific philosophy. It refers to the concept that natural processes observed in the present day also occurred in the past. The idea applies to pedological (soil) and sedimentological processes, and the environmental parameters that govern the distribution of plants and animals. For example, we can observe today that *Alnus glutinosa* (common alder) inhabits wet areas, such as fens and marshes, and the edges of rivers, ponds, and lakes. If we find subfossils (e.g., flowers and seeds) of alder in either geological or archaeological deposits, then we can confidently assume that wetland habitats existed near to the site in the past. Although there are instances where this principle is questionable (e.g., history of *Taxus baccata* (yew) woodland; Branch et al., 2012), the application of uniformitarianism and other universal laws governing natural processes, means that environmental archaeology is a truly scientific discipline. The existence of universal laws directing human behavior is a matter of considerable debate, and principles such as uniformitarianism are undoubtedly less valuable when trying to explain archaeological phenomena. Nevertheless, recognition of the scientific basis of archaeology (see Pitt-Rivers (1827–1900), Morgan (1818–81), and Taylor (1832–1917)), especially from the 1930s, led eventually to the formulation of a new theoretical framework known as *processualism* in the 1960s (see Binford, 1968; Clarke, 1978). This paradigm shift in archaeology led to an innately scientific approach to research (Renfrew and Bahn, 2000), involving multidisciplinary studies and further complex theoretical developments, such as systems theory (Flannery, 1968; Brothwell and Higgs, 1969). Although succeeded by *postprocessualism* as the dominant paradigm in archaeology (see Archaeology, Theory in), environmental archaeology maintains a science-based approach, which seeks to understand the relationships between the biological and physical environment, and social and economic changes (Butzer, 1982).

Subdivisions of Environmental Archaeology

The fields of geoarchaeology, zooarchaeology, archaeobotany, and geochronology form the basis of environmental archaeology, and are part of a wider subject area known as archaeological science, which includes the study of human remains, materials science, conservation, and geophysics. These fields embrace the study of ancient sediments and soils, and fossil plant and animal remains, recovered from a wide variety of *archives*, which may be located in a diverse range of environments – terrestrial, marine, and ice. *Archaeological archives* are those located on settlement or occupation sites, irrespective of the length or nature of the human activities; they include rubbish and storage pits, postholes, drainage ditches, moats, wells, postholes, cesspits, hearths, and ancient buried soils, as well as the archives listed below. In contrast, *Geological archives* have no known evidence of occupation but may nevertheless provide important information on environmental change due to natural processes and human impact, and the broader environmental context of human activities; these typically include peat bogs and lakes, floodplains and valleys, as well as marine sediments and ice. Environmental archaeologists therefore utilize many of the field and laboratory methods used in biological and earth sciences, and data generated by

quaternary scientists, especially in the fields of paleoclimatology and paleoecology.

Geoarchaeology

Geoarchaeology, and the *geoarchaeologist*, is concerned with landscape and stratigraphic formation (e.g., sedimentary events and soil processes) and modification processes (i.e., deposit alteration), and draws mainly on geological, sedimentological, and soil science analytical techniques used in the field and laboratory (Dincauze, 2000; Branch et al., 2005). The primary role is therefore to record the physical characteristics (e.g., color, dryness, wetness) and composition (e.g., organic matter content and type (e.g., moss, herbaceous and wood peat, or lake sediment), and particle size (gravel, sand, silt, clay)) of stratigraphy in archaeological and geological archives. This information is then used to reconstruct and explain the events or processes responsible for the formation of the stratigraphic sequence, including postdepositional transformation. Recognition of the boundaries between *units* of stratigraphy (or *contexts*) is a critical part of this procedure because these may define changing depositional processes, both cultural and natural, and the relative rate of change, i.e., a *conformable boundary* (gradual change), and an *unconformable boundary* (rapid change).

Geoarchaeologists therefore utilize a wide range of analytical procedures to record and interpret stratigraphy, including standard approaches for sediment and soil description and classification, and laboratory methods, such as micromorphology, particle size analysis, magnetic susceptibility, and multielement geochemistry. Using these procedures, and applying uniformitarian principles, geoarchaeologists can assign sedimentary units to a specific natural process. For example, Riddiford and colleagues (2012) by analyzing a complex series of sediments in the Seille Valley (NE France) have been able to reconstruct the changing patterns of river channel formation, migration, and abandonment during an extended period of human settlement. The introduction of a human component into stratigraphic formation provides an additional complexity, and understanding the relationship between the event or process and the morphology of the deposit often presents a significant challenge even with the range of analytical procedures available. This is particularly apparent in archaeological sites where multiple phases of human occupation involving domestic and industrial activities (e.g., Tell Brak, Syria) result in a diverse range of deposits associated with ditches, pits, latrines, structures, and demolition debris (Matthews, 2003). Nevertheless, these procedures are particularly successful for a range of common depositional environments and their sedimentary deposits (**Table 1**).

Particle size and geochemical analyses, in particular, are two key approaches used to characterize stratigraphy in terms of not only formation processes but also past social and economic activities. Both techniques define the geological source of the sediments and soils examined, and hence susceptibility to weathering and erosion of parent material, and resultant mineral grain size (sand, silt, and clay) and elemental composition. Economically, these characteristics help to define the agricultural potential of soils, especially their cropping capability, drainage, level of biological activity, and nutrient status, as well as the management history of the soil profile (e.g., manuring regimes) and finally the sustainability of the farming system. For example, sandy soils (silica-rich rocks) with a low pH (acid) have less agricultural potential, especially for the growth of crops, than alkaline soils, derived from calcium carbonate-rich rocks, which have a higher pH (e.g., Gale and Hoare, 1991). For example, the study of ancient agricultural terraces in the Peruvian Andes using these methods has enhanced understanding of soil quality, manuring regimes, and nutrient status (e.g., Kemp et al., 2006). Phosphorus is a key elemental indicator, and enhanced values in soils (by absorption) on habitation sites suggest waste materials associated with human and animal activities (e.g., Parnell et al., 2002). The analysis of soils and sediments in thin section (micromorphology) permits examination of microscopic characteristics, especially minerals and inclusions, and is especially important

Table 1 Common depositional environments and their sedimentary deposits

Alluvium – water-borne sediments, mainly fine-grained (clay and silt), and deposited in lowland river systems either on the floodplain (over-bank deposits) or within former river and stream channels. The most extensive deposits are Holocene in age (last 11 700 years) but they also commonly occur in previous glacial and interglacial periods (e.g., Brown, 2003).
Colluvium – slope wash depositing unsorted sediment on the sides and bottoms of dry valleys mainly due to gravity and farming practices. The particle size is highly variable and greatly depends on the source parent material (e.g., Wilkinson, 2003).
Windblown sediments – sand (e.g., dunes) and silt (e.g., loess) deposited by wind action within open, poorly vegetated landscapes, and desert and dry temperate environments, as well as former periglacial zones.
Marine sediments – present within intertidal zones and coastal wetlands, and mainly fine-grained mineral sediments. These sediments have been used successfully to record periods of Holocene sea level rise (marine transgression), and to investigate the relationships with ecosystem and societal change (e.g., Bell et al., 2000).
Glacial sediments – there is a wide variety of sediments of glacial origin, many of which are unsorted and, therefore, composed of a range of particle sizes, including gravel, and associated with glacial landforms, such as moraines. Those sediments located within periglacial environments, such as river sands and gravels, and solifluction deposits, are occasionally associated with archaeological remains, such as Paleolithic tools (e.g., Hosfield, 2011).
Volcanic sediments – these are represented by a range of particle sizes (pumice, lapilli, ash) when deposited proximal to the source (e.g., Vesuvius and the Roman town of Pompeii; Sigurôsson et al., 1982) but often fine-grained tephra distal to the volcano. The latter, either occurring as visible tephra layers or as cryptotephra (nonvisible), is especially useful as chronological marker horizons in both archaeological and geological archives.
Organic sediments – mainly peat forming in fens, raised bogs, and blanket bogs and composed of mosses, herbaceous remains and wood and organic-rich lake sediments (gyttja). The waterlogged, anaerobic conditions provide an excellent environment for the preservation of archaeology, and subfossil biological remains (e.g., Branch et al., 2012).
Cave sediments – comprise a mixture of well-stratified water-borne and aeolian sediments, and rock fall. Caves are particularly attractive for human habitation during the Pleistocene and Holocene resulting in deep stratigraphy often composed of domestic waste, hearths, and stabling deposits.

for identifying human modification of soil sequences (e.g., manuring), use of space (e.g., stabling, flooring), and the inclusion of materials into cultural units (e.g., bedding, feces, fodder, charcoal, ash, plant material). Geoarchaeologists also utilize the magnetic susceptibility of soils and sediments to test for burning, the addition of heated materials, and the natural weathering of soils. It plays a useful role, therefore, in the detection of activity areas on habitation sites, as well as identifying erosional events in the catchment areas of lakes (see Thompson and Oldfield, 1986; Dearing, 1999).

Zooarchaeology

Zooarchaeology, and the *zooarchaeologist or archaeozoologist*, has a central focus on human subsistence of both wild and domesticated animals (*paleoeconomy*), but also broader environmental reconstruction (*paleoenvironment*), such as changes in climate and vegetation cover (*see* Zooarchaeology). The goal, therefore, is to enhance knowledge of the impact of humans on the natural environment, and the effects of natural environmental changes on humans, including the economy, diet, and daily life of human communities. This requires the use of a range of analytical methods, and the application of experimental and ethnographic data (*see* Ethnoarchaeology), to obtain independent lines of complementary scientific evidence from both archaeological and geological archives, and their sedimentary deposits (*see* Geoarchaelogy above).

The most common vertebrate remains found within archaeological and geological archives are bones (e.g., fish, small and large mammals). They can be identified to ascertain the genus or species, wild or domesticated, the type of bone (e.g., femur), and the sex and age of the animal. These data permit understanding of human economy and diet, in particular hunting and husbandry practices, pathologies, and enable reconstruction of past environments. In addition to the quantitative methods, such as bone measurement and weight, measurements of stable carbon ($\delta^{13}C‰$) and nitrogen ($\delta^{15}N‰$) isotope ratios of collagen, lipids, and cholesterol in human bone and tissue have improved understanding of the importance of terrestrial and marine food, the use of exotic food, and changing dietary patterns. In addition, analyses of oxygen isotopes ($\delta^{18}0$) in animal bone phosphate that correspond to local meteoric water values (drinking water of the animals) and mean annual air temperature have provided quantitative reconstructions of past climatic regimes.

Mollusca preserved on land (e.g., soil and mires), and in freshwater (e.g., lakes), brackish water (e.g., high salt marsh), and marine (e.g., estuaries) sediments provide three categories of information useful to environmental archaeology: (1) broad paleoenvironmental reconstruction, (2) human impact on the natural environment, and (3) human economy and diet, which is mainly (but not exclusively) confined to shellfish. For example, in the UK, hillslope sediment (e.g., Bell, 1983) and calcium carbonate-rich sediment (spring chalk) has provided rich sources of information on past human environments. The exploitation of marine mollusks has provided valuable information on subsistence practices, including diet, seasonality, technological developments, and trade (e.g., Rick and Erlandson, 2000; Mannino and Thomas, 2001; Cabral and da Silva, 2003). For example, at Ysterfontein (South Africa), a coastal cliff shelter, evidence has been provided for the exploitation of shellfish, including black mussel and granite limpet, as well as tortoise, cape dune molerat, and jackass penguin among many other animals, enabling the reconstruction of human exploitation strategies and population levels during the Middle Stone Age (*c*.60–40 000 years ago) (Halkett et al., 2003). Insect remains provide unique paleoclimatic records using the mutual climatic range method (Atkinson et al., 1986; Hellqvist and Lemdahl, 1996), as well as information on human and animal diet, the function of archaeological features, the condition of human and animal mummified remains, and the contents of offerings (e.g., Panagiotakopulu, 2001). For example, insects associated with urban archaeological deposits in York (UK) have provided precise data on local environmental living conditions and human activities. Investigators established six main groups of insects that commonly co-occurred in specific contexts in the past: (1) inside buildings and dry ('house fauna'), such as dry plant debris, wood borers, the human flea, and stored products; (2) foul decaying organic matter, rich in ammonia, commonly found in stable manure; (3) foul decaying organic matter, associated with moist ground; (4) very foul conditions; (5) cesspits; and (6) wool cleanings. These groups also highlighted the complex interpretational problems associated with single archaeological layers (e.g., floors) containing insect assemblages from several habitats, reflecting a range of human activities (e.g., Carrott and Kenward, 2001).

Several lesser groups of zooarchaeological remains are worthy of note. Ostracoda (aquatic invertebrates), like diatoms (below), are highly sensitive to changes in salinity with three main assemblages identifiable: freshwater ($<0.5‰$; lakes, rivers, and ponds), brackish water (0.5–30‰; lagoons and salt marshes), and marine (30–40‰; oceans and seas), as well as rainfall, temperature, and alkalinity. They are valuable in archaeology as indicators of changing coastline morphology and the height of relative sea level. Foraminifera are unicellular organisms with a well-known ecology. Different species occupy niches in marine environments according to food availability, levels of predation, type of sediment, light penetration, water temperature, and salinity, and thus are useful indicators of changes in water depth, salinity, and climate in coastal environments. Cladocera are microscopic animals (arthropods) with an ecology divided into two broad groups based upon their ecological preferences: (1) offshore planktonic species and (2) inshore littoral species. They are useful for reconstructing temperature and precipitation, and erosion due to human activity (e.g., Jeppesen et al., 2001). The application of Cladocera analysis to environmental archaeology is still in its infancy, but the technique clearly has enormous potential. For example, analyses of Cladocera from 26 lakes in Poland, and one in Croatia, have enabled reconstruction of climate change, lake level oscillations, nutrient status, and chemistry. It was concluded that lake water nutrient levels increased during phases of human settlement due to the deposition of refuse into the lake (Szeroczyńska, 2002).

Archaeobotany

Archaeobotany, and the *archaeobotanist*, also focuses on human economy and diet, but also environmental change. The most

common plant remains found on archaeological sites are seeds that have been charred (exposure to heat, e.g., hearth) or waterlogged (exposure to excess moisture, e.g., ditch, moat, well), and to a lesser extent mineralized (replacement by salts, e.g., cesspits), desiccated (exposure to extreme aridity), or preserved as pottery impressions. For example, Old World cereal grains (e.g., species of wheat and barley) might be found with charred or mineralized parts of the plant, such as straw. In geological archives, seeds are mainly preserved in a waterlogged state (e.g., lake sediments, peat). For example, remains found in peat indicate plants growing on the surface of the peat, while those found in lakes represent plants found within the wider landscape and the lake margin, and may provide valuable information on climate change or vegetation history. In contrast, remains found in archaeological archives provide essential information on the economy, diet, and daily life of the site's occupants, irrespective of whether they are hunters and gatherers or from agricultural communities. In the case of the latter, paleoeconomic, experimental, and ethnographic studies of Old World charred cereals and their associated components have made significant contributions to our understanding of the origin, spread, distribution, methods of cultivation, and processing techniques of these important food resources (e.g., Weiss and Kislev, 2004). Waterlogged seeds from archaeological deposits provide useful information on local flora, presence of standing water, animal husbandry, and the presence of cultivation (e.g., Ponel et al., 2000). For example, several lake-village sites in France and Switzerland have provided evidence for transportation to the site of plants exploited by humans for animal fodder, human food, and building materials (e.g., Rasmussen, 1993).

Palynology, the analysis of pollen grains and spores, is a widely used technique in environmental archaeology and provides valuable information on vegetation composition, structure and succession, plant migration, climate change, human modification of natural vegetation cover, and land use. They are highly resistant to decay and optimal conditions occur in acidic (low levels of microbial activity) or anaerobic (oxygen free), waterlogged archives, although pollen is also preserved in dry conditions, such as whole, desiccated coprolites (feces), and cave sediments. Identifying human impact is a key application of pollen analysis and requires the recognition of indicator species or groups of particular forms of land use, such as cultivation, pasture, and meadow, as well as deforestation and woodland management. For example, records showing a decline in tree pollen values or individual tree taxa, the presence of certain ruderal weed species strongly associated with cultivation or pastoralism, cultivated species of crops and taxa indicated managed woodland indicate a transition to agriculture, or the intensification of agriculture, in many world regions (Branch et al., 2005).

The presence of microscopic charred particles in archaeological and geological archives often complements pollen studies and provides useful information on natural wildfires (including climate history), human-induced woodland clearance, agricultural practices, and woodland management. For example, investigations of peat and lake sediments have frequently provided a rich source of information on human-induced woodland disturbance caused by burning (e.g., Moore, 2000). At North Gill, Yorkshire (UK), radiocarbon-dated fine pollen analysis combined with plant macrofossil and charred particle analysis has provided detailed information on woodland clearance (Innes and Blackford, 2003). Combined with fungal spore analysis, especially taxa that grow on the feces of domesticated animals (*Sporormiella*, *Cercophora*, *Coniochaeta*, and *Chaetomium*), the data have provided unequivocal evidence for linkages between woodland disturbance and forest grazing (Innes and Blackford, 2003). Macroscopic wood preserved by waterlogged conditions or burning is also often found in both archives, and provides primary data on woodland composition, and hence vegetation history, woodland management, agricultural practices (e.g., cultivation of plants for fodder and bedding for animals), woodland exploitation for domestic fires (fuel), and material culture (wooden artifacts) (e.g., Asouti, 2003).

Two further key categories of archaeobotanical remains epitomize the diverse range of methods available. Diatoms are unicellular algae with different species occupying the bottom of (benthic), or floating within (planktonic), water bodies. Preservation occurs in a wide range of archives of environmental archaeological interest, including lakes, alluvium, salt marshes, and ditches, and indicative of a variety of past environmental conditions (e.g., marine, brackish, or freshwater) that reflects prevailing temperature, salinity, pH, oxygen, and mineral content. For example, diatoms in lake sediments have provided valuable records of accelerated erosion due to deforestation during the last 6000 years, which in turn has caused changes in lake trophic (nutrient) status. Deep alluvial sequences in lowland river valleys (e.g., Lower Thames, UK) have also recorded changes in diatom assemblages due to fluctuations in the height of relative sea level during the Holocene (e.g., Battarbee, 1988). Finally, phytoliths are opaline silica bodies produced by plant cells and preserved in several archaeological archives, namely hearths and the sediment fills of caves, pits, and coprolites. Phytoliths may provide valuable information on past vegetation cover (e.g., the presence of meadow and pasture), the cultivation of crops (e.g., maize), and the presence of herbivores (e.g., within dung). For example, one of the most detailed recent studies of phytoliths has been concerned with the history of maize (*Zea mays*) domestication and cultivation in the New World, and especially extending the known range of prehistoric cultivation into southern parts of South America, e.g., southeastern Uruguay (Iriate, 2003).

Geochronology

To enable comparison of environmental archaeological data within and between archaeological and geological archives requires the application of dating methods that aim to provide both accurate and precise ages for the stratigraphy recorded, as well as establishing the duration of an event. By applying the universal law of superposition (a unit overlying another must have formed later), the *relative chronology* is often understood. Perhaps the most important of the so-called *absolute chronology* (precise age or date) techniques is radiocarbon dating (^{14}C; radiometric and accelerator mass spectrometry), but also optically stimulated luminescence, thermoluminescence, electron spin resonance, uranium–thorium ($^{234}U/^{230}Th$) and lead 210 (^{210}Pb) dating have all provided important chronological frameworks for

environmental archaeological evidence (e.g., Aitkin, 1990; *see* Chronology, Stratigraphy, and Dating Methods in Archaeology).

Research Themes

There are numerous excellent examples of where environmental archaeology has been enlightening, and readers are directed to the following key journals: *Environmental Archaeology*, *Journal of Archaeological Science*, *Geoarchaeology*, *Vegetation History and Archaeobotany*, *The Holocene*, and the following sample textbooks: Butzer, 1982; Branch et al., 2005. Case studies cover a broad range of themes and geographical areas, over a variety of spatial (local to global) and temporal scales, from the short term (<100 years) to the long term (>10 000 years). Collectively, site-specific data contribute to greater regional understanding, and occasionally, individual records provide something of unique, international importance. For example, peat cutting for fuel and horticulture has uncovered human bodies remarkably well preserved in the anaerobic, waterlogged conditions. These bodies provide a valuable insight into the daily lives of people in the past, and especially their diet, health, nutrition, and cause of death (see Stead et al., 1986). Data have emerged from geological archives that highlight the influence of climatic events over the past 10 000 years on socioeconomic developments in the Mediterranean (e.g., Drescher-Schneider et al., 2007; Berger and Guilaine, 2009; Mercuri et al., 2011), North and South America (e.g., deMenocal, 2001) and West Asia (e.g., Mithen and Black, 2011). For example, in northern Italy, climate change is considered to be a possible cause for initiation of terrace agriculture *c*.4200 years ago (Branch, 2013), while in northern Britain climate change may have caused the collapse of agricultural practices during the Bronze Age (Tipping et al., 2008). This theme, in particular, epitomizes one of the major ongoing challenges for environmental archaeology, namely understanding past human resilience and adaptation in the face of climate and environmental change.

A further illustration of a significant, long-term theme is the global origins and spread of agriculture (Thorpe, 1996; Harris, 2010). Environmental archaeological studies over several decades have demonstrated the existence of multiple centers of plant and animal domestication. While the timing of the transition to farming varied considerably, there is nonetheless unequivocal evidence in each location for morphological and genetic alteration of many of the food staples that remain important today (*see* Chronology, Stratigraphy, and Dating Methods in Archaeology). For example, the broad timing of plant domestication in West Asia (e.g., wheat, barley, rye, lentils, and peas) and Southeast Asia (e.g., millet and rice) was ~10 000 years ago (Kya), while in Australasia (e.g., yam and banana) and North Africa (e.g., millet and sorghum) it was ~7Kya and ~4–3Kya respectively. In North America (e.g., squash and sunflower) it was ~5Kya, Mesoamerica (e.g., squash and maize) ~10–8Kya, and South America (e.g., squash, arrowroot, yam, cotton, sweet potato, beans, peanut, manioc, chili pepper, potato, and quinoa) ~10–5Kya. The subsequent spread of agriculture across these geographical areas, traced by environmental archaeological data, has quantified the magnitude of impact on the natural environment, especially the creation of new ecosystems, due in many respects to increased human population levels and technological developments. This resulted, directly and indirectly, in animal extinctions, deforestation, soil degradation and erosion, afforestation, and the formation of mires, grasslands, and shrublands (heathlands and moorlands).

In Western Asia, arguably the most intensively studied region, agricultural origins have been linked to both climate change at the transition from the last glaciation to the present interglacial (Holocene), and a continuum of human interaction with plants and animals. In many areas, significant landscape modification accompanied the transition to farming, including woodland clearance and water management systems. During the subsequent spread of agriculture across Europe over ~6000 years, woodland clearance became increasingly apparent, complementing evidence for woodland exploitation for fuel, fodder, bedding, and construction. Although many records suggest that clearance was temporary ('shifting cultivation'), which permitted the woodland to recover, the general trend was progressive deforestation of mature coniferous (e.g., fir) and/or deciduous (e.g., elm, lime, oak) woodland, and the introduction of field systems and in some areas agricultural terracing. For example, the so-called 'elm (*Ulmus*) decline,' and later 'lime (*Tilia*) decline,' were two events linked to woodland clearance (e.g., 'slash and burn'), for both cereal cultivation and the harvesting of leaves, bark, and twigs for fodder and bedding. Both were part of a mixed economy involving animal husbandry and cultivation, and possible woodland management (pollarding). The subsequent development of grasslands and shrublands illustrate the long-term effects of degradation due to intensive and extensive human activities, with the development of Northern European heathlands, Mediterranean macchia/maquis, and lowland temperate grassland. The African savannah, American prairies, and Asiatic steppe have similarly been cited as plagioclimax communities (created and maintained by human activities) whose origins relate to sustained human intervention and management for many millennia.

The widespread impact of agriculture, in terms of environmental degradation, landscape modification, and societal resilience, therefore, remains a key global theme. In South America, for example, evidence for landscape modification is epitomized by the development of raised fields and terracing, with an estimated ~1 000 000 ha of terracing in Peru alone (see Branch et al., 2007). Terracing transformed the morphology of the landscape while also creating the basis for a highly innovative and sustainable agricultural system that primarily permitted the cultivation of maize and quinoa. Studies have permitted detailed investigations of the terrace structural organization and development, especially their irrigation and drainage. This work has revealed multiple phases of terrace construction during later prehistory, with evidence for possible soil enrichment through manuring and/or fallow periods, and localized landscape erosion triggered by the construction activities. Interestingly, there is evidence in several parts of Peru for the abandonment of terraces, such as those of the Wari civilization (AD 500–1000), and their subsequent reconstruction prior to the Colonial Period (AD 1533). While the persistence of terrace agriculture confirms the importance of

terraces in the agricultural system, the precise reason for their unsustainability remains unclear. In contrast, in Mesoamerica, the collapse of agriculturally intensive practices of raised field agriculture and terracing due to nutrient depletion and soil erosion has been strongly associated with the demise of the Maya civilization (Branch et al., 2005).

In summary, future environmental archaeological research will, therefore, focus on major methodological developments and key themes of regional and global significance. A primary research area will be improvements to the precision of key dating methods; this will ensure a better understanding of the timing and duration of major cultural and environmental changes, and will be crucial if we are to explain whether natural environmental change, such as climatic oscillations, caused social and economic change in the past, or if this was triggered by purely cultural factors. The origins and spread of agriculture, and the environmental impact of agriculture, will also continue to be major research areas, as will changing human diet, nutrition, and health; these linked themes permit better understanding of past food security, and the sustainability and resilience of societies in a changing world, which will be pertinent to present day concerns and debates surrounding global climate and environmental change.

Environmental Attitudes and Behavior: Measurement

Abstract

The conservation of our planet's natural ecosystems and resources is one of the greatest challenges of the twenty-first century. As most environmental problems are caused by human activities, effective environmental policies depend on reliable and valid information about these behavioral patterns and their determinants. For this reason, the theoretical background, internal logic as well as (dis)advantages of two dominant strategies for assessing environmentally relevant behaviors are presented: the intent- and impact-oriented measurement approaches. We conclude by discussing the measurement of environmental concern and empirical findings regarding the environmental concern–pro-environmental behavior relation.

Introduction

John lives in a semidetached house in a small village just outside a medium-sized town. He owns a small car, but he tries to use his bike as much as possible. In his garden, he has a compost bin, and he makes sure that he always separates his glass, chemical, and paper waste. Usually, he buys organic food, and he does not eat meat more than twice a week. He recently replaced his old washing machine with a highly efficient one. He actively participates in demonstrations against the planned enlargement of a nearby airport and for this reason has voted for the Green party in the last elections. Because of his interest in African landscape and culture, in his holidays he frequently travels to this continent.

Mark lives in a small flat in the town center. He would like to own a car, but because parking space is rare, he does not buy one. Mark throws all his waste into the same bin. He prefers to buy frozen food, which he heats up in his microwave oven. Mark is not interested in politics and did not vote in the last elections. He hates traveling and uses his holidays to stay at home meeting friends in local pubs.

Who would you believe to be more environmentally friendly, John or Mark? Probably most people would label John 'more pro-environmentally' because he consciously tries to perform pro-environmental behaviors. Mark obviously does not care much about the environment.

However, from an objective impact-oriented point of view, Mark's household behavior may be less environmentally damaging because he does not own a car, lives in a small flat that requires less energy to heat, and most importantly, does not travel long distances by plane.

The example, adapted from Gatersleben et al. (2002), not only illustrates the complexities associated with the analysis of environmentally related behaviors but simultaneously reflects the two strategies we can find in the literature regarding the measurement of these behaviors: The intent-oriented approach uses the actor's standpoint for defining pro-environmental behavior. An action is viewed as pro-environmental behavior if it is taken with the intention to benefit the environment. It stresses an actor's subjective motivation as a defining characteristic of pro-environmental behavior.

In contrast, the impact-oriented approach associates all human activities with more or less negative environmental impact (e.g., energy and water use, waste production). As a consequence, the question is not whether a specific human action is 'pro-environmental' by intent but how serious its objective environmental impact is. Thus impact-oriented measures seek to identify target behaviors that significantly influence the environment and examine how the environmental impact of behavior patterns can be reduced.

Types of Environmentally Relevant Behavior

The introductory example also shows the multitude of behavioral domains where a person can articulate his or her intention to protect the environment. For this reason, Stern (2000) suggests to differentiate three main types of pro-environmental behavior: (1) pro-environmental activism (e.g., active involvement in environmental organizations and demonstrations), (2) nonactivist behaviors in the public sphere (e.g., petitioning on environmental issues, joining or contributing to environmental organizations, and supporting public policies), and (3) private-sphere environmentalism. Because of its immediate impact on the environment, researchers have focused mainly on the last behavioral type: the purchase, use, and disposal of personal and household products. It is useful to further subdivide these private-sphere behaviors according to the type of decision they involve: (1) the purchase of major household goods and services (e.g., cars, houses), (2) the use and maintenance of environmentally important goods (e.g., heating and cooling systems), (3) household waste disposal (e.g., composting), and (4) 'green' consumerism (e.g., purchasing organic food). Research based on such distinctions has revealed that the purchase of cars and major household appliances tends to have much greater environmental impact than changes in the level of use of the same equipment.

Led by the assumption that all these behavioral types reflect one common latent pro-environmental behavioral tendency, researchers for a long time expected a positive correlation between these different types of pro-environmental behavior. However, empirical research does not support this assumption. For example, Bratt (1999) found only weak, sometimes even

negative, correlations between different pro-environmental consumer activities. He concludes that there is no 'general' pro-environmental behavior: A person can behave very pro-environmentally in one behavioral domain (e.g., recycling) and very environmentally damaging in another (e.g., mobility). This behavioral heterogeneity and inconsistency has stimulated research. For example, Diekmann and Preisendörfer (1998) identified cognitive strategies that help individuals to harmonize and reconcile their seemingly incongruent behaviors. They called these strategies 'attention-shifting strategy' and 'low-cost strategy.' When attention shifting, people tend to emphasize the importance of some activities while simultaneously playing down the importance of other activities. The basis of the low-cost strategy is that "compliance to 'environmental morality' and 'ecological insight' in low-cost situations can be qualified as a cognitive mechanism to harmonize environmental attitudes and behavior" (Diekmann and Preisendörfer, 1998, p. 89). According to this logic, pro-environmental behaviors tend to be consonant with each other where the cost of pro-environment behavior is low. Bratt (1999) argues that people experiencing cognitive dissonance because of environmentally harmful behaviors that are difficult or costly to change (e.g., taking flights, eating meat) may engage in 'simple and painless' pro-environmental behavior as a means to relieve the discomfort created by these harmful behaviors. Holland et al. (2002) assume that this type of self-justification is based on the general acceptance of a 'contribution ethic.' This contribution ethic implies that neglecting a specific pro-environmental behavior is justified if one is already 'playing one's part' in other ways – leading one to 'rest on one's laurels.' For example, Thøgersen (1999) found that whenever people felt less obliged to do one specific thing (e.g., consider the waste consequences of their packaging choices when shopping), they often did something else to address the problem (i.e., sort household waste for recycling).

Measuring Private-Sphere Environmentalism – The Intent-Oriented Approach

Typically, intent-oriented private-sphere environmentalism measures incorporate behaviors that are seen as prototypical indicators of a person's latent motivation to act in a pro-environmental way. Respondents are provided with a list of such behaviors and asked to indicate how often (e.g., on a scale ranging from 'never' to 'always') they perform each of these behaviors. While some studies focus on one specific behavior, such as recycling (e.g., Schultz and Oskamp, 1996) or mobility (e.g., Van Lange et al., 1998), others deploy scales that combine different types of behavior (e.g., Kaiser, 1998).

A measure developed by Preisendörfer (1998) for the national survey 'Environmental Concern in Germany' provides a good demonstration of the logic underlying the intent-oriented approach as well as the results typically obtained within this approach. In this survey, face-to-face interviews with 2307 persons randomly drawn from the German population were conducted. Environmentally relevant behaviors were assessed using a list of 16 questionnaire items distributed across four subscales (**Table 1**): (1) four items assessed recycling behavior with respect to different materials, (2) four items assessed different aspects of pro-environmental shopping behavior, (3) four items assessed energy- and water-saving behavior, and (4) four items assessed aspects of mobility and transportation behavior. The results of the statistical analyses provide empirical evidence that the item sets used for assessing the behavior dimensions recycling, shopping behavior, and mobility/transportation behavior form homogeneous subscales. However, the statistical analyses indicate that the four items of the subscale energy- and water-saving behavior do not form one homogenous dimension, but two independent dimensions.

Table 1 Preisendörfer's (1998) intent-oriented 16-item pro-environmental behavior scale

Recycling behavior	*Shopping behavior*
Recycling of paper (v28a)	Buying products with eco-label (v12)
Recycling of glass (v28b)	Buying products with less packaging (v19)
Recycling of aluminum (v28e)	Buying seasonal fruits/regional vegetables (v20)
Recycling of batteries (v28f)	Buying organic food (v21)
Energy- and water-saving behavior	*Mobility and transportation*
Use of energy-saving bulbs (v36)	No car in household (v49d)
Reducing water-consumption under shower (v39)	Weekend trips without car (v66)
Use of water-saving installations (v40)	Last holiday trip without car/airplane (v68)
Turning down heating when going out (v44)	Shopping without car (v70)

Adapted from Jann, B.R.A., 1998. Zur Messung des Umweltverhaltens (Unpublished Master Thesis). Department of Sociology, University of Bern, Swiss, p. 21.

As discussed above, this study also suggests that participants' responses to the four subscales should be viewed as representing distinct behavioral tendencies as opposed to only one single homogeneous behavioral tendency: The intercorrelations of the four subscales are not only weak, but the mobility subscale actually correlates negatively with the other three subscales. A smallest-space analysis conducted by Jann (1998) with the intercorrelations of all 16 items as input offers detailed insights into the structure underlying participants' response patterns. **Figure 1** shows the spatial structure of the items: the mobility items are positioned at the left edge of the figure, the shopping and recycling items at the right edge. Furthermore, the items form a circle, however, one with significant gaps. With the low-cost hypothesis (Diekmann and Preisendörfer, 1998) as theoretical background, Jann (1998) interprets the circular structure as representing the costs associated with the performance of behaviors assessed by the four subscales. Consequently, the circle leads from situations with low behavioral costs (recycling) to situations with high behavioral costs (mobility) with energy saving in between.

The intent-oriented approach of measuring pro-environmental behavior has been criticized mainly for two reasons. One critical point is its reliance on self-reported behavior, which may not be an accurate measure of actual behavior. Instead, self-reported behavior tends to reflect people's perceptions or beliefs about their behavior, at least to some degree. Factors such as lack of knowledge, social

Figure 1 Two-dimensional smallest-space analysis plot of the intercorrelations of Preisendörfer's 16-item pro-environmental behavior scale. Adapted from Jann, B.R.A., 1998. Zur Messung des Umweltverhaltens (Unpublished Master Thesis). Department of Sociology, University of Bern, Swiss, p. 22.

desirability, and other types of (conscious or unconscious) response bias may result in inaccurate reports of actual behavior. For example, in Preisendörfer's (1998) survey, 24% of the participants reported that they always or often bought organically produced food. But at that time the share of organically produced food on the total food production in Germany was only about 2%, which questions the reliability and validity of participants' self-reported ecobehavior. Several studies, however, suggest that the difference between self-reported behavior and actual behavior is not systematic (Fuijii et al., 1985). Moreover, Kaiser et al. (1999) could show that people were only marginally tempted to give socially desirable answers in a study on pro-environmental behavior.

Another critique (e.g., Stern, 2000) relates to the way scales of pro-environmental behavior are usually constructed. Intent-oriented scales often include behaviors (e.g., refusing plastic bags in shops or buying recycled paper) that do not reflect the actual environmental impact of persons or households. As a consequence, respondents reporting a large number of these insignificant actions often receive a high total pro-environmental score, although such actions may only have a marginally positive impact on the environment.

Measuring Private-Sphere Environmentalism – The Impact-Oriented Approach

The impact-oriented approach is based on an analysis of the actual environmental load of household consumption activities. For this purpose, elaborated input–output energy analysis and life-cycle assessment methods are used to calculate the objective environmental load of household consumption activities, mainly in energy and/or greenhouse gas emission terms (for an overview of these methods, see Kok et al., 2006). The aim of these analyses is to both calculate average per capita energy use or CO_2 emissions and identify the consumption activities most significantly contributing to this total amount. For Germany, for example, this kind of analyses indicates an average yearly per capita output of approximately 11 t of CO_2 (UBA, 2007). On average, 25% of these CO_2 emissions come from heating and electricity, 23% from transportation, and 14% from food. That leaves 28% for other consumption and 10% for public infrastructure. The activities that most strongly affect a household's total CO_2 emissions are transportation – distances traveled by car and plane – and housing – size of living area and insulation standard. Food consumption also has a significant impact on CO_2 emissions, in particular the quantity of meat consumed and the purchase of organically produced food.

Based on these analyses, impact-oriented survey questionnaires cover the consumption activities (purchase and use) most relevant for a household's total CO_2 emissions. Work by Gatersleben et al. (2002) provides a good example of this strategy. In two large field studies among randomly selected Dutch households ($Ns = 2167$ and 1250), respondents were asked which household goods they possess (e.g., tumble driers, dishwashers, cars) and how often they use them per day, month, and year. Responses were weighted by estimates of

the average energy use needed for such behaviors. Using this measure, in the first study the average total energy use of respondents' households was estimated as 140 GJ, which is 61% of the mean total energy use of 229 GJ indicated by the official 1995 Dutch energy statistics. In the second study, the estimated average total energy use was 152.4 GJ, which is 67% of the actual total household energy use.

In another study, Gatersleben (2001) reports a more detailed analysis of the external validity of this measurement approach. For this purpose, 393 Dutch participants completed a computer-based questionnaire asking a total of 72 questions about their possession and use of household goods. Respondents were also asked for their annual gas and electricity use as indicated on their annual bill. Only 252 respondents (64%) were able to respond to this question. A correlation of $r = 0.45$ was found between gas use estimated by the 72 questions about their possession and use of household goods and the actual gas use reported in the bill, which means that 20% of the variance in actual gas use was measured by the indicator variables assessed in the computer-based questionnaire. Actual and estimated electricity use correlated $r = 0.51$, which means that 26% of the variance in actual electricity use was measured. Apparently, even the long list of 72 household consumption activities did not cover all the activities significantly contributing to a household's total energy use.

From the practitioner's perspective, another development of the impact-oriented measurement approach is interesting: the development of Internet-based personal CO_2 calculators. The German Federal Environment Agency (http://uba.klima-aktiv.de/) provides a German version of such a personal CO_2 calculator, Warwick University (http://carboncalculator.co.uk/users.php) offers a British one, and the Environmental Protection Agency (http://www.epa.gov/climatechange/ghgemissions/ind-calculator.html) has developed a calculator for the US. These calculators ask people to enter data regarding their household's energy consumption (heating and electricity) and transport as well as questions about their personal food consumption. All calculators report tons of CO_2 emitted per year by these household activities as the central outcome.

Summing up, how can we evaluate the impact-oriented approach of measuring pro-environmental behavior? Especially in the form of Internet-based individual CO_2 calculators, this approach provides a valuable instrument to examine the environmental impact of different household activities. For citizens and policy makers, the integration of knowledge from the natural and social environmental sciences results in more practically relevant information. By using dependent measures such as energy use in gigajoules or CO_2 emissions, the effects of current household activities as well as changes of these activities can be expressed in quantifiable units that have a meaning for policy makers and citizens.

One clear disadvantage of the impact-oriented approach is its high complexity. The information needed for calculating a household's total energy consumption requires elaborate and detailed questionnaires. Sometimes, people cannot supply the requested information. For example, many people are not able to report their annual consumption of natural gas in cubic meters or electricity in kilowatt-hour. The same is true for the reporting of travel and nutrition habits. As a consequence, many CO_2 calculators use raw national average estimates as substitutes. Furthermore, valid and sufficient indicators for assessing the indirect energy use resulting from the important 'other consumption' domain are currently missing. Other problems relate to the conversion factors used to calculate the energy use and CO_2 emissions resulting from the reported household activities. These conversion factors depend on steadily changing parameters such as the national or regional electricity mix (use of fossil, nuclear, or renewable energy sources for electricity production) or the energy efficiency of technology available to households. The results of different CO_2 emission calculators can thus vary considerably for the same input data, due to differences in calculating methodologies, behavioral estimates, or conversion factors (Padgett et al., 2008).

The Relation between Intent- and Impact-Oriented Measures

In the current literature, only very few studies explicitly analyze the empirical relationship of the two described strategies for measuring pro-environmental behavior. Two studies by Gatersleben et al. (2002) are rare exceptions. In their first study, they correlate two self-report measures of pro-environmental behavior (purchase of organic or regional food products and recycling behavior) with their estimate of household total energy use. The authors find a negative correlation between the estimated total household energy use and self-reported recycling behavior ($r = -0.24$, $p < 0.01$). However, there is no correlation between the purchase of environmentally benign food products and the estimated total household energy consumption ($r = -0.04$). In their second study, self-reported pro-environmental behavior was assessed via a scale consisting of 13 behaviors (e.g., turn down thermostat, travel short distances by bike, eat vegetarian food). In this second study, the correlation between the self-reported performance of the 13 pro-environmental behaviors and the estimated total household energy use was $r = 0.22$ ($p < 0.001$). This implies a significant but weak relation between self-reported frequency of pro-environmental behaviors and the household's total energy consumption. However, there may be a methodological reason for this weak relation: Whereas total energy use was measured on the level of the household, pro-environmental behaviors were measured on an individual level. Thus, it is not clear how much the total household energy consumption reflects the behavior of the respondent or that of other household members. It would be worthwhile to conduct studies in which self-reported pro-environmental behavior is also measured on the household level by collecting data on pro-environmental behaviors from all household members individually. This may then result in a closer correspondence of both measures.

Environmental Concern

In the 1970s, the notion that environmental problems are the consequences of 'maladaptive human behavior' (Maloney and Ward, 1973) motivated social scientists to analyze individual motives underlying this behavior. One central

assumption of this early research was that environmentally harmful behaviors reflect a person's low degree of environmental concern. Since then, most researchers conceptualize environmental concern as a general attitude, which comprises cognitive, affective, and conative judgments concerning the object of environmental protection (e.g., Weigel and Weigel, 1978). A measurement scale developed by Preisendörfer (1998) for the survey 'Environmental Concern in Germany' discussed previously exemplifies this approach. Based on substantive considerations and results of explorative factor analyses, this environmental concern scale consists of the nine statements presented in **Table 2** covering the cognitive (insight into the endangerment), the affective (feelings of fear, anger), and the conative component (willingness to do something). Preisendörfer constructed an additive index of environmental concern and standardized the range of this index to 0–20. The mean of the index in Preisendörfer's study was 13.1 and Cronbach's alpha was 0.72. Preisendörfer (1998) reports that the correlation between this environmental concern scale and the 16-item index of pro-environmental behavior discussed above is only $r = 0.22$. This low correlation fits with the results of meta-analyses summarizing the results for a great number of studies testing empirically the relationship between environmental concern and specific pro-environmental behaviors. In most of these studies, intent-oriented scales were used for assessing pro-environmental behavior. In their meta-analysis, Hines et al. (1986) report an average correlation of $r = 0.35$ (128 studies); Eckes and Six (1994) report an average correlation of $r = 0.26$ (17 studies). Taken together, the general attitude regarding environmental concern seems to explain not more than 10% of the variance of specific environmental behaviors.

Table 2 Preisendörfer's nine-item environmental concern scale

	−	−/+	++
Affective Dimension			
I am afraid when I think about environmental conditions for future generations.	8	18	74
If we continue our current style of living, we are approaching an environmental catastrophe.	11	23	66
Watching TV or reading in the newspaper about environmental problems, I am often embarrassed and angry.	11	26	63
Cognitive Dimension			
The great majority of German people do not act in an environmental responsible way.	13	29	58
There are limits of economic growth, which the industrialized world has already reached or will reach very soon.	10	34	56
* In my opinion, environmental problems are greatly exaggerated by proponents of the environmental movement.	54	27	19
Conative Dimension			
It is still true that politicians do much too little to protect the environment.	8	26	66
To protect the environment, we should be willing to reduce our current standard of living.	11	35	54
Environmental protection measures should be carried out, even if it reduces the number of jobs in the economy.	36	37	27

Note: Five-point response scale: − strongly disagree/disagree, −/+ partially disagree/partially agree, ++ strongly agree/agree; numbers related proportion of respondents in percent; * disagreement is seen as indicating higher environmental concern.
Adapted from Diekmann, A., Preisendörfer, P., 2003. Green and greenback: the behavioral effects of environmental attitudes in low-cost and high-cost situations. Rationality and Society 15, p. 455.

There are various theoretical approaches that have been developed for explaining the low relation between general environmental concern and specific pro-environmental behaviors. For example, Guagnano et al. (1995) introduced the A-B-C model, which combines insights from social psychological attitude theory and sociological rational choice theory. This model predicts an interaction effect "… where the main effect of attitudes [A] on behavior [B] depends on external conditions [C], with the effect of attitude approaching zero when external conditions are very strongly positive or negative" (p. 704). The A-B-C model was empirically supported in a field experiment with curbside recycling. The low-cost hypothesis by Diekmann and Preisendörfer (1998, 2003) states "… that environmental concern influences ecological behavior primarily in situations and under conditions connected with low costs and little inconvenience for individual actors. The lower the pressure of costs in a situation, the easier it is for actors to transform their attitudes into corresponding behavior" (p. 443). Diekmann and Preisendörfer (2003) provide evidence for the low-cost hypothesis using survey data from Germany. Their findings show that environmental concern has a stronger effect on low-cost behavior (such as recycling or buying products with eco-labels) than on high-cost behavior (such as shopping or going on holiday without a car).

According to Bamberg (2003), the weak direct relationship between general environmental concern and specific environmental behaviors is due to an inadequate understanding of how general attitudes influence specific behaviors. Because it is a situation-invariant general 'orientation pattern,' environmental concern cannot influence specific behaviors directly. Only the situation-specific cognitions concerning the consequences associated with a specific behavior are direct determinants of this behavior. Bamberg consequently suggests a framing model of the environmental concern–environmental behavior relationship (for a similar idea, see Lindenberg and Steg, 2007): This framing model assumes that as a general attitude, environmental concern influences specific behaviors only indirectly. More precisely, environmental concern influences a person's 'definition of the situation' that is how she or he frames a decisional problem, the relevant behavioral alternatives, and the personally important consequences associated with these alternatives. **Figure 2** presents the results of a study by Bamberg (2003) empirically supporting the framing model: Situation-specific cognition, conceptualized via Ajzen's (1991) theory of planned behavior, is a strong determinant of a specific pro-environmental behavior (actually requesting an information brochure about 'green' electricity products). After taking into account this situation-specific cognition, general environmental concern no longer has any direct effect on intention or behavior. But as expected, environmental concern has a substantive direct effect on the perception and evaluation of the situation-specific cognition, especially the personally salient behavioral consequences.

Figure 2 Behavior-specific constructs mediating the environmental concern–behavior relation. NB = normative beliefs; BB = behavioral beliefs; CB = control beliefs; Att = attitude toward the behavior; SN = subjective norm; PBC = perceived behavioral control; I = intention; B = behavior; * = not significant. Adapted from Bamberg, S., 2003. How does environmental concern influence specific environmentally related behaviors? A new answer to an old question. Journal of Environmental Psychology 23, 21–32; Note: Results are based on structural equation modeling (standardized path coefficients and explained variances); abbreviations relate to constructs from the theory of planned behavior (Ajzen, I., 1991. The theory of planned behavior. Organizational Behavior and Human Decision Process 50, 179–211.).

Conclusion

The ultimate goal of most studies on pro-environmental behavior is to provide information that can be helpful in reducing the negative environmental impact of human activities. In this context, it is important to be aware whether these studies use an intent- or impact-oriented approach. Intent-oriented measures focus on behaviors that are environmentally significant from an actor's point of view based on societal notions of environmentally significant behaviors. With these measures, what respondents deliberately do to benefit the environment, why some people act more pro-environmentally than others, and what can be done to persuade people to behave more pro-environmentally, for instance, could be examined. However, currently used intent-oriented measures tend to neglect behavior patterns with a strong objective environmental impact. Identifying the human activities with the strongest environmental impact is the focus of the impact-oriented measurement strategy. Here, knowledge from the natural and social sciences is integrated, more adequately reflecting the nature of most environmental problems. Furthermore, by using dependent measures such as CO_2 emissions, the impact-oriented approach usually yields more meaningful and thus more practically relevant information for citizens and policy makers. Impact-oriented measures are also more suitable for understanding how a household's total energy use is influenced by contextual factors (e.g., available technologies, infrastructures) whose impact is often hidden and outside of an individual actor's awareness or influence. Thus, impact-oriented measures are usually the better choice for studies interested in investigating how current living styles support or prevent sustainable behavior. The strategy used for assessing environmentally relevant behavioral patterns may also influence which predictors a study empirically identifies as the most important (Gatersleben et al., 2002). Using an intent-oriented measure, a study may find that psychological variables (e.g., perceptions, attitudes, values) are the most important determinants. Using an impact-oriented measure, a study may find that structural variables (e.g., income, type of car, house size) are most important. Research results regarding the environmental concern–pro-environmental behavior relation also underline the importance of these infra- or contextual factors. In the meantime, there seems to be general agreement to treat environmental concern as a general decisional precondition for considering the potential environmental impact of decisions rather than a direct predictor of actual behavior. Whether or not the more pro-environmental option is actually chosen depends on its subjectively perceived behavioral consequences (e.g., costs or inconvenience).

In closing, we want to mention that from our point of view, one central task of interdisciplinary environmental research will be to develop measures that integrate the advantages of the intent- and impact-oriented approaches. For this purpose, a list of reliable indicators would have to be developed that covers a substantial amount of variance in the actual environmental impact of a household without resulting in a questionnaire that is too long or demanding for the respondents.

Abstract

Our decisions shape the environment, affecting what is preserved, destroyed, restored, and ignored. The environment shapes our decisions, affecting our health, economics, and well-being. These diverse decisions are often complex and uncertain. As a result, there is no unifying theory of environmental decisions. Rather, the social and behavioral sciences offer a repertoire of methods, results, and theories that, together, can describe environmental decisions with the requisite richness. They draw on two distinct research traditions: holistic approaches, seeking organizing patterns in those decisions and the people who make them, and reductionist approaches, seeking to assemble pictures by building on existing results. As a result, environmental decisions offer a venue for applying, testing, and extending the social and behavioral sciences, as well as integrating their work with that in the natural sciences.

Individuals' primary interaction with the natural environment is through their senses. They form feelings and impressions that both shape and are shaped by their basic cognitive structures and values. At deeper levels of processing, they form more explicit beliefs and attitudes, including theories and ideologies (Atran, 1990; Kahneman, 2011). These cognitions, perceptions, and attitudes affect both their own well-being and that of their environment. People feel better in a healthy environment and feel better knowing that their environment is healthy (De Young and Princen, 2012). Conversely, the health of that environment depends on choices that people make, as consumers, workers, citizens, officials, tourists, or industrialists (Garner and Stern, 1996; Kates et al., 2012). Indeed, even natural scientists studying the environment are increasingly realizing that understanding human behavior is essential to their work, both to identify the drivers and effects of environmental change, and to make that research useful (Levin and Pacala, 2005; Mooney et al., 2013).

Environment-related decisions are enormously varied, in the options, uncertainties, consequences, and decision-makers involved – not to mention their national, social, cultural, institutional, and economic settings. As a result, there is no simple summary of what people want, believe, feel, or do, relative to the environment. For example, over the past decade, in the United States, overt concern over climate change has increased, more or less, steadily for Democrats, while drifting downward for Republicans. On the other hand, overt behavior related to climate change has often tracked its own course, independent of those attitudes, with climate change 'deniers' often being relatively proactive in adopting energy conservation measures – but reflecting economic concerns, rather than environmental ones (Krosnick et al., 2006; Leiserowitz, 2006). Given the diversity of environmental decisions, this article focuses on approaches to studying *how* people address them, rather than on *what* they do about specific ones – except as illustrative examples.

Research Strategies for Describing Environmental Decisions

Environmental decisions are not only diverse, but also often complex, with many options, outcomes, uncertainties, and decision-makers. As a result, doing justice to any specific decision requires accommodating the details of its case study. Scholars grounded in the humanities have produced many such accounts, in fields such as environmental writing (Slovic and Dixon, 1992), retrospective technology assessment (Tarr, 1996), environmental history (Cronon, 1992), and cultural anthropology (Douglas, 1966). Their detailed observations shape and constrain the theories of social and behavioral scientists, in their quest for general accounts, capturing regularities in environmental behavior found across individual cases. Those scientists can adopt one of two basic compromises in their research approach.

1. *Holistic* approaches look for recurrent behavioral archetypes, in the sense of groups of people who respond in predictable ways (e.g., Cotgrove, 1982; Schwartz, 2006). For example, they might attempt to identify 'ecofreaks,' who resolutely oppose any intrusion into pristine areas, or 'technocrats,' who automatically dismiss such concerns. 'Cultural theory' pursues this approach, seeing whether people can be characterized by their positions on two dimensions and, if so, whether that characterization predicts their attitudes and behaviors (Dake, 1992; Douglas and Wildavsky, 1982). The ongoing 'Six Americas' project categorizes people by their positions on climate change, finding patterns of beliefs, attitudes, and behaviors, arrayed across the spectrum of Alarmed-Concerned-Cautious-Disengaged-Doubtful-Dismissive (Maibach et al., 2011). Moral Foundations Theory (Haidt, 2012) describes people by their orientation on five or six dimensions, such as their respect for 'authority' and their sanctification of 'purity' (as those general properties are defined by their social group).
2. *Reductionist* approaches assume that all people respond to the same factors, but interpret and weigh them differently, sometimes leading to different choices (Edwards, 1954). For example, all people may sometimes rely on the *availability heuristic*, inferring the likelihood of future events based on how easily they can remember or imagine them happening. However, they may reach different conclusions, if they have observed different events or have different powers of imagination (Tversky and Kahneman, 1974).

Similarly, all people learn how to extract the gist of recurrent events, but may be exposed to different events and receive different instruction in what to observe (Reyna, 2012). All people have sacred values, which they will only compromise under duress; however, which those are depends on their culture and social groups (Atran, 2002). Thus, from a reductionist perspective, ecofreaks and technocrats (if such archetypes exist) are otherwise similar people, who have been shaped by different social pressures and material conditions.

Holistic and reductionist accounts coexist in *dual-process* theories of attitude and cognition (Kahneman, 2011; Evans, 2003), which posit parallel processes involving a general orientation toward a stimulus (e.g., an environmental cause, scene, or insult) and a detailed analysis of its contents (Slovic, 2010). That general orientation might be guided by holistic general themes or by reductionist general concerns. The more detailed analysis might overturn those impressions or be constrained by them, as can happen when people fall prey to the many cognitive processes that favor initial beliefs. For example, people may disproportionately seek confirmatory, rather than contradictory evidence; resolve ambiguity in favor of current beliefs; or exaggerate the definitiveness of small samples of evidence (Gilovich et al., 2002). How hard people work to analyze an issue should depend on how important it seems, what return they expect from that effort, and how great is their general need for cognition – reflecting and shaping their opportunities to affect the environment.

Some researchers favor holistic accounts in principle, because they lament the richness lost when behavior is reduced to the expression of general processes. They may be especially skeptical of processes identified in the rarefied settings of experiments crafted to highlight phenomena that interest investigators. Conversely, some researchers favor reductionist accounts in principle, because they need the rigor of experimental evidence regarding clearly defined processes. They might have little patience with the 'grounded theories' that emerge from the immersion that one holistic methodology requires (Charmaz, 2006), unnerved by the limited intersubjectivity that such accounts require. When researchers respect both holistic and reductionist approaches, the tension between them can provide rich accounts, while posing healthy challenges to each. The next section discusses how to realize that potential.

Holistic Accounts

A general account of environmental behavior is useful only if researchers can unambiguously translate complex real-world situations into its necessarily abstract terms. For holistic theories that translation process may itself be holistic, attempting to identify specific cases with theoretical archetypes, such as a particular kind of intergroup conflict, stage of social-economic development, or level of civic engagement (Atran, 2002; De Young and Princen, 2012; Fischhoff, 1995; Kates et al., 2012). Holistic interpretation allows observers to use any available data to elaborate their account. Moreover, if those observers write well, the coherence of their narrative should help readers to retain and integrate the details of their analyses. Archetypes are a natural way to organize evidence, even if that sometimes means neglecting discordant details.

Unfortunately, holistic interpretation also allows observers to exploit the richness of the evidence, in order to fashion accounts that are more convincing than the evidence warrants. For example, they might exploit the privileged position of hindsight to select and interpret facts that affirm their theories (Fischhoff, 1975), perhaps arguing that particular decisions predictably led to success or ruin. Or, they might strategically identify people and groups with archetypes, obscuring inconsistent beliefs, attitudes, and behaviors. Moreover, the very act of categorizing other people is an exercise of power. It may reduce them to stereotypes, while flattering observers as possessing superior insight and even morals, as they reveal others' failings – feeding the natural tendency to create simplistic views of other people (Dawes, 1988; Nisbett and Ross, 1980).

These possibilities are not lost on the partisans in environmental conflicts, who value opportunities to demean their opponents and flatter their allies. As a result, they may seize on holistic accounts in the research literature, and then spin them to their own end, perhaps even loosely citing studies ('X has shown that the public is irrational about nuclear power'). Indeed, scientists can acquire a political following because of the conclusions they reach, independent of the strength of their evidence. For example, the British Conservative government was accused of establishing its Behavioral Analysis Unit, not because it understood the science (Thaler and Sunstein, 2009), but because it sought cover for antiregulatory policies, by claiming that people could be 'nudged' to protect themselves (House of Lords, 2011). The narrative character of holistic accounts means that both scientific and amateur ones have the same outward form, forcing readers to check their scientific pedigree (Funtowicz and Ravetz, 1990). What training did the authors have? What peer-review screens did their work pass? Who paid for the work? (Oreskes and Conway, 2008; Hoffman, 2010) As in other domains where science enters public discourse, environmental researchers bear a special responsibility to ensure that their work is interpreted appropriately.

If the behavioral archetypes that recur in holistic accounts are clearly defined, then it should be possible to operationalize them in individual-difference measures (e.g., Dake, 1992; Dunlap, 2013) If such measures pass conventional psychometric criteria (e.g., reliability, construct validity), then they allow testing predictions derived from the underlying theory (e.g., "corporate greens have deeper commitment to consumption-related issues"; "environmental pessimists have greater scientific knowledge and institutional distrust"). Like other empirical tests, these are only as sound as the *auxiliary assumptions* underlying them, such as how people perceive the costs and benefits of possible actions (e.g., Do pessimists and optimists interpret the same facts differently or possess different facts? Are people vulnerable to framing effects, such that their preferences depend on how the issues are presented?). Here, reductionist approaches can help, by assessing the plausibility of those assumptions ("that information is widely distributed, so most people should have seen it"; "people have stable preferences about such things, so framing shouldn't have much effect") or by measuring them directly

(e.g., finding similar preferences with alternative frames) (Fischhoff, 2005).

If archetypes cannot be measured authoritatively, then individuals may be characterized by observable features, such as their gender, race, income, or nationality – at the price of substituting general social theories for the theoretical force of archetype-based ones. For example, African-Americans typically express relatively great concern over environmental problems (Vaughan, 1993). That could reflect their greater exposure to those problems (meaning that they have more reason for concern), as documented by the environmental justice movement (Schlosberg, 2007). Or, it could reflect greater awareness of their immediate surroundings, greater physiological sensitivity, greater suspicion of social institutions, or poorer resources for self-protection, among other things. A similar array of hypotheses follows from Slovic's (1999) finding that most Americans have similar environmental attitudes, except for some white males, who trust technology more and worry about the environment less than other people. Characterizing the subset of white males responsible for this overall group difference is a starting point for a theory of archetypes, sorting out the experiences or circumstances that create these distinctive views.

Reductionist Approaches

Analogous measurement issues confront reductionist approaches, looking at how common behavioral patterns emerge in diverse settings. For example, approaches grounded in decision theory ask how individuals evaluate possible actions in terms of their expected effects on valued outcomes (Edwards, 1954; Fischhoff and Kadvany, 2011). Those outcomes might affect the well-being of individuals (e.g., taxes, wilderness opportunities, social status), their society (e.g., public health, justice, property rights), or their environment (e.g., biodiversity, reproductive success). In these accounts, actions are attractive to the extent that they increase the chances of good outcomes and decrease the chances of bad ones.

Although they adopt a rational-actor perspective for characterizing the elements of decisions, these approaches vary widely in terms of how far they expect such normative analyses to be descriptively accurate. At the one extreme, lie economic theories that envision well-informed individuals calculating the discounted lifetime stream of goods flowing from different choices. At the other extreme, lie psychological approaches that envision individuals driven by emotions and uncompromising sacred values. The contrast between those choices and analytically optimal ones shows the price that people pay for their nonrationality (Breakwell, 2014).

Such research readily accommodates the heterogeneity of environmental decisions and the importance of specific outcomes in them. For example, social norms may loom large for curbside recycling, where neighbors can see what one does, but not for roadside littering when no one is looking. Thus, while it may be tempting to make general statements of the form 'what matters to people, when it comes to the environment is X,' they always need to be qualified by specifying the context in question. For example, people may not litter even when alone, if they have internalized that behavior as a social norm, have made it a habit, or always fear watching eyes. Even for as important a topic as valuing human life, studies have found widely varying willingness to pay for reducing the probability of premature death (Tengs, 1995; Viscusi, 1992).

As a result, behavior appears most consistent in specific domains, such as home energy conservation (Gallagher and Randell, 2011). There, studies often find that conservation increases when people perceive greater benefits, lower costs, and fewer barriers to change. Although such results might seem just to affirm commonsense, they are needed to establish how general behavioral processes play out in specific settings: Are specific incentives (e.g., cost saving) strong enough to motivate specific energy conservation behaviors? How well did consumers understand those incentives (perhaps buried in their electricity bills)? To what extent did extrinsic incentives undermine intrinsic ones (e.g., environmental concern), by diluting the statement made by prosocial actions? Did consumers have realistic ways to save? Were they in a state of energy poverty, so that lower costs allowed them consume the energy needed for basic well-being (e.g., more tolerable indoor temperatures)?

Thus, as with holistic approaches, reductionist ones must assess the beliefs and values of the individuals whose behaviors they hope to explain, predict, or manipulate. Even a valid model may fail, if its terms are measured poorly. However, that problem is less acute for models with an additive, or 'compensatory,' structure, in which good and bad expectations can cancel one another out (e.g., the health belief model, the theory of reasoned action). Because such models are relatively insensitive to errors in measurement (Dawes, 1988) they will have some predictive validity as long as a study includes rough approximations of the factors affecting behavior (or variables correlated with them). Unfortunately, that very robustness limits these models' explanatory value, because many versions will produce similar predictions. As a result, it is hard to tell, which variables drive behavior and how important each is. That concern applies less with *noncompensatory* decisions, where one consideration overrides all others, as with sacred values. For example, there may be no way to overcome the stigma from contaminating part of the natural world – or to diminish the moral high ground from protecting it (Douglas and Wildavsky, 1982; Flynn et al., 2002; Baron and Spranca, 1997).

Evaluating Perceived Risks and Benefits of Environmental Changes

Assessing beliefs and values is a central activity for the disciplines of cognitive and social psychology. Assessing them for environmental issues has not only drawn on that basic science, but also extended it. For example, some environmental decisions involve unfamiliar processes (e.g., radiation, invasive species, climate changes) playing out unevenly over time and species (Levin and Pacala, 2005). Those decisions may pose fateful trade-offs, where individuals cannot rely on tradition or trial and error to decide what is right: What should we pay to protect endangered species, poor children from lead in their homes, or groundwater from contamination? How should we weigh what our children (and grandchildren) might think about our choices? Such decisions may leave people uncertain

about themselves as well as about their world, asking 'what do I want?' as well as 'what can I get?' Assessing and reducing both kinds of uncertainty has prompted social and behavioral scientists working on environmental issues to break new research grounds.

More or less formally, that research begins by analyzing the decisions that people face, in order to get the facts right and to focus on the right facts – in the sense of the ones that matter most (Baron, 2012). Those analyses take an 'inside view,' trying to see the world the decision-makers face (Kahneman, 2011), reducing the risk of researchers assuming that others share their environmental concerns or exaggerating their store of common knowledge (Dawes, 1988; Nickerson, 1999). Unlike science education, where experts determine which facts are worth knowing, the study of environmental decisions depends on individuals' circumstances, goals, and capabilities (Fischhoff, 2013).

Having characterized a decision, the research proceeds to assess how well individuals understand it, contrasting what they know with what they need to know, in order to make sound choices. That contrast may reveals gaps in their understanding about the world or about themselves. One strategy for avoiding decision-specific studies is to create tests of environmental 'literacy.' Their usefulness depends on whether they include facts that people *need to know* or just ones that it would be *nice to know*. For example, studies of energy conservation have found that people can know about many measures that make some difference without knowing which make a real difference or how to defend their choices against critics or temptations (Moser and Dilling, 2007). Researchers in science education have learned much about the knowledge and skills needed to master a domain (Klahr, 2000). Analogous studies are needed to identify core understandings that create the mental models that allow individuals to interpret diverse environmental decisions. Those might include having an intuitive grasp of how gases diffuse, how risks mount up through repeated exposure, how to use numbers, or how to apply decision-making rules.

Whereas environmental science can establish the clearest possible picture of how decision will affect outcomes that people value, it cannot determine which outcomes those should be. That depends on what matters to those making the decisions. Scientists can, however, ask how successful those people have been in constructing stable preferences for specific environmental choices, consistent with their basic values. That test recognizes that, even when a topic is familiar (e.g., declining fish populations, invasive species, suburban sprawl, vector-borne disease), the trade-offs posed by a specific choice often are not (e.g., a ballot measure, housing decision, a restaurant meal). As a result, individuals cannot just 'read off' a response, from a universal utility or value function, as naïve rational-actor models might hold. Rather, they must 'articulate' or 'construct' their preferences among the options on offer – or perhaps even create new ones (e.g., expanding their housing search).

In such cases, where individuals are not sure what they want, researchers seeking to elicit attitudes and preferences face a choice. They can either take people as they are, perhaps with fragmentary views, or help people to reflect on the issues so as to derive fuller positions. The former strategy risks a sin of omission, if people are swept along by the incomplete set of issues evoked by their initial thinking on the topic. The latter strategy risks a sin of commission, if suggesting alternative perspectives biases decision-makers' thinking, rather than deepening it. The two strategies draw on complementary research traditions. The former has roots in psychophysical research, the latter in decision theory.

Eliciting Environmental Beliefs and Attitudes

Psychophysical Measurement

Emerging from the natural sciences, early psychology focused on what came to be called *psychophysics*, determining the psychological equivalent of physical stimuli. These studies envisioned physiological and psychological mechanisms that translated stimuli into internal states of arousal. If asked, individuals can report on that state, with a word, number, or action (e.g., pressing on a handgrip to show their confidence, adjusting a rheostat to show the light intensity equivalent to the loudness of a tone) (Poulton, 1989).

The most straightforward applications of psychophysical approaches to environmental decisions pose questions such as how natural (or attractive or inspiring or calming) a natural scene is. Researchers might elicit direct ratings (Daniel and Vining, 1983) or similarity judgments, if they hope to capture attitudes that people have difficulty expressing, because they lack the words or hesitate to use them (Cantor, 1977). The less familiar a task, the greater the burden on researchers to ensure that it was interpreted as intended: which features were noticed – and overlooked? What did respondents believe about the *ecosystem services* (Daily, 1997) that the environment in question provides and the peril it faces? Did respondents sense (intended or inadvertent) hints regarding what to say? How real or hypothetical did the task seem? It takes a suite of converging studies, with suitable manipulation checks, to establish what environmental changes people believe they are evaluating, how deep their understanding is, and what they mean by their responses (Fischhoff and Furby, 1988).

Such interpretative issues have been at the center of the long-running controversy over *contingent valuation* (CV), a method advanced by some resource economists for monetizing 'goods' not traded in marketplaces where their economic value could be observed (e.g., atmospheric visibility, the survival of endangered species) (Carson and Hanneman, 2005; Mitchell and Carson, 1989). In the psychophysical tradition, CV interviewers ask people how much they are willing to pay in order to prevent an adverse environmental change (or how much they will demand as compensation for it). These responses are meant for use in cost–benefit analyses, where they could represent environmental changes that would otherwise be neglected in policy-making dominated by economic analyses. Whether a CV study captures respondents' preferences depends on how well they can understand and answer questions demanding explicit, quantitative evaluations of complex, novel stimuli with many potentially relevant details.

CV studies illustrate the strengths and weaknesses of eliciting attitudes toward environmental goods. Respondents' ability to provide some answer to any question suggests that they have some relevant feelings on any environmental issue.

However, feelings alone may not predict what they would pay where there is a market market for that environmental good (Kahneman et al., 1999). One focal research topic is whether CV judgments are properly sensitive to the amount (or 'scope') of the change being evaluated (Arrow et al., 1993). The death of one migratory bird saddens many people, while the death of many birds saddens them even more. However, the differences in those feelings may not be commensurate with the difference in their value (Slovic, 2010). Insensitivity to scope can be invoked as measurement failure. One defense is that people might give as much to 'adopt-a-bird' as to an avian conservation program, if they believe the former to be more effective or assume that other people will adopt the other birds.

However orderly such judgments might be, some critics question the propriety of asking them at all. They argue that monetization 'anaesthetizes moral feeling' (Tribe, 1972), by reducing everything to putative economic equivalents. As a result, CV may win some battles for the environment, by gaining recognition for some otherwise neglected changes, but lose the war, by failing to defend the environment's intrinsic value.

Decision Theoretic Measurement

The early days of the modern environmental movement confronted many technologies with public opposition that their proponents could not, and perhaps would not, understand. One natural response was (and still is) to claim that a technology's opponents overestimate its expected fatalities. Early studies examined that claim by eliciting fatality estimates, finding (1) a strong correlation between lay and statistical fatality estimates; (2) higher estimates for technologies with more 'available' deaths, relative to others with similar statistical frequency; (3) consistent ordinal estimates across response modes; and (4) inconsistent absolute estimates, across response modes. Thus, people seem to have a fairly robust feeling for relative fatalities, which emerge however such (unusual) questions are asked (Lichtenstein et al., 1978). However, they have a poorer feeling for what numbers to use, which makes their absolute judgments sensitive to the contextual cues that a response mode provides (Poulton, 1994).

However, quite different judgments emerged when lay respondents made judgments of 'risk,' rather than of 'average year fatalities.' Moreover, those judgments better predicted their attitudes (e.g., how strictly they should be regulated) (Slovic et al., 1979). Many studies have examined what other aspect of 'risk' affects people. One early candidate was that people give added weight to a technology's 'catastrophic potential,' in the sense that they see greater 'risk' when many lives could be lost at once. Anecdotal support for that hypothesis can be found in the attention drawn to plane crashes and public concern over nuclear power – despite lay respondents' recognition that, in an average year, the death toll from nuclear power is negligible. Studies found, however, that what really bothered people about catastrophic accidents was the uncertainty that made them possible (Slovic et al., 1984). Those two 'risk attributes,' catastrophic potential and uncertainty, embody quite different ethical principles. Avoiding catastrophes means caring how deaths are distributed (over time and space), hence preferring small-scale technologies (other things being equal). Avoiding uncertainty means being risk averse, hence requiring stronger evidence before accepting new technologies.

The study of attributes that define 'risk' can be traced to Starr's seminal (1969) claim that, for any level of benefit, the public tolerates a higher fatality rate for risks incurred voluntarily (e.g., skiing) than for risks imposed involuntarily (e.g., electric power). As evidence, Starr placed eight activities in a risk–benefit space, based on estimates of their annual fatalities and economic benefits, and then sketched parallel 'acceptable risk' lines, an order of magnitude apart, for voluntary and involuntary ones. Such a *revealed preference* analysis assumes that members of a society are satisfied with the risk–benefit trade-offs that they see around them. A study (Fischhoff et al., 1978) testing this hypothesis asked lay people to judge 30 technologies in terms of their current risks and benefits, as well as rating those risks in terms of their acceptability, voluntariness, and eight other attributes (e.g., catastrophic potential, dread, controllability, known to science, known to the public). It found:

1. a weak correlation between lay judgments of current risks and benefits (indicating that respondents saw no greater benefit from riskier technologies);
2. no greater correlation between judgments of current risks and benefits after controlling for judgments of the risk attributes (indicating no double standards for voluntary and involuntary risks, nor for any other attribute);
3. a belief that most technologies had unacceptably high risks (indicating that current trade-offs did not reveal respondents' preferences);
4. a strong correlation between judgments of current benefits and acceptable risks (indicating a willingness to make risk-benefit trade-offs);
5. a willingness to accept higher risk levels for voluntary risks, holding benefits constant, and for other risk attributes (indicating a double standard).

In addition to their substantive content, such studies demonstrate the importance of disciplining speculations about environmental beliefs, attitudes, and behaviors with direct empirical evidence.

Applying Behavioral Research

Setting Public Policy

If robust, such social and behavioral science results can guide public policies affecting the environment. The studies just mentioned suggest that the public will accept risk–benefit trade-offs – which might surprise critics who claim that the public demands zero risk. They show where lay and expert judgments of risk and benefit diverge; hence they must be reconciled through better analysis or better communication. They show risks attributes to consider when designing technologies and regulations. They clarify the ethics embedded in seemingly technical terms. For example, 'mortality risk' can be summarized as 'probability of premature death' or as 'days of lost life expectancy.' The latter measure puts a premium on deaths of young people (where many days are lost with each life), whereas the former treats deaths equally

(Crouch and Wilson, 1982; Fischhoff and Kadvany, 2011). Similarly, any measure of mortality risk (and any policy dependent on it) must either consider (or ignore) how equitably risks are distributed across population groups – and, if so, which groups matter and what 'equitably' means. By raising these questions, behavioral research reveals assumption hidden in the conventions of risk and benefit analysis, so that they can be actively considered in policy making.

Considering a large set of risk attributes makes policy-making more complicated and, potentially, too unwieldy to include public input. One simplification strategy looks for redundancy among risk attributes, and then focuses on a few canonical concerns. For example, if dread risks also tend to have catastrophic potential, then considering either attribute will lead to similar policies. Studies have, in fact, found that two factors can account for much of the variance in ratings of the attributes. One seems to reflect how well risks are understood, the second how much they are dreaded (Fischhoff & Kadvany, 2011). Characterizing multiple risks in terms of the same attributes allows comparisons across domains, and increases the chances for consistency (H.M. Treasury, 2005).

A second strategy accepts the complexity and works with people to master its details. The need for credible resolution of environmental disputes has prompted many consultative bodies to advocate proactive public involvement (e.g., Blue Ribbon Commission, 2012; Presidential-Congressional Commission, 1997). In one important initiative, the US Environmental Protection Agency (Davies, 1996) fostered some 50 state and regional consultations to set priorities among risks. In them, public representatives set the agenda, while technical experts gathered and explained relevant evidence. Dietz and Stern (2008) provide an authoritative summary of the science of public participation.

Ensuring Citizen Competence

Because behavioral and social science research seeks to understand and overcome the limits to lay decision-making, it also provides answers to a critical policy question: Are individuals competent to make sound choices – or should those be left to experts and officials (Lupia and McCubbins, 1998)?

Motivated answers to that question are common. A competent public serves the interests of those seeking active public participation or deregulation (and a marketplace where the public fends for itself). An incompetent public serves the interests of those who favor expert opinion and strong regulation (to protect a defenseless public). Behavioral research can provide a disciplined decision-specific answer, comparing what people know with what they need to know. Sometimes, fragmentary knowledge is enough to identify the best course of action. Sometimes, even extensive knowledge is inadequate and people need help.

Behavioral research can also expand the public's envelope of confidence by filling critical gaps in their knowledge. At times, people need specific facts (e.g., the payback period for improved home insulation, the probability of a nuclear core meltdown). In that case, there is a *supply curve* for information (to use the economic term), arranging facts in order of decreasing usefulness for distinguishing among decision options. Doing so uses recipients' attention wisely and respectfully, starting with the things that they most need to know. At other times, people need to understand the processes shaping environmental changes. In that case, communications must complete their mental model, so that they can follow the action, see when things have changed, and devise effective responses.

Behavioral research can also assess the competence of experts and provide ways to elicit their judgments more systematically (Kammen and Hassendzahl, 1999; O'Hagan et al., 2006). When even the most knowledgeable experts are highly uncertain, a case may be made for moving slowly – unless doing so allows even more poorly understood processes to go unchecked. For example, the debate over genetically manipulated organisms has revolved on whether anyone understands them well enough to make sound choices. Those who doubt that even the experts know enough to proceed often invoke a 'precautionary principle' – at times as sign of distrust, at times as a demand for deeper analyses of uncertainty (Löfstedt et al., 2002).

Conclusion

Environmental decisions are enormously diverse and often enormously complicated and uncertain. Individuals can have a hard time grasping the issues and deciding how they feel about them. Understanding and reducing such difficulties is part of the challenge and opportunity for researchers studying environmental decision-making. Driven by the importance of these problems, environmental social scientists have cast a wide net, adopting and inventing both holistic and reductionist approaches, drawing on diverse research streams. Their work makes it possible to go beyond speculation and anecdotes to systematic evidence regarding what people believe and want regarding their environment. Its fate and, with it, their own depend on how well they understand what is happening and realizing their desires for its future. Behavioral and social science research can help them, identifying new research topics along the way.

Environmental Conservation and Development: Critical Perspectives

Scott Freeman, George Washington University, Washington, DC, USA

Abstract

Starting in the 1960s, environmental movements brought global attention to humanity's negative effects on the natural environment. Governments and international organizations became increasingly concerned with addressing these environmental problems. This article examines arguments about how and why environmental degradation occurs and discusses the critical literature at the intersection of environmental conservation and international development programs. While interventions are often well intended, many bring with them the unintended negative effects of population displacement, marginalization of indigenous communities, and questionable economic benefits. Future policies and programmatic interventions must be subject to rigorous research and critique in order to improve their effects on local populations and the environments.

Detrimental logging, mining, contamination of drinking water, desertification, and air pollution constitute widespread environmental degradation and have incited global concern. Not only have environmental problems become more visible and publicized since the 1960s, they have galvanized worldwide response. Environmental movements have inspired governments, individually and through international accords, to address degradation (Leach and Fairhead, 2000). Local and global nongovernmental organizations (NGOs), as well as multilateral entities such as the United Nations (UN) and the World Bank have made priorities of environmental sustainability and conservation. Resulting parks and protected areas, biodiversity conservation initiatives, and broad schemas to regulate and monitor environmental pollution and consumption have arisen in the late twentieth century. Many of these initiatives have aligned themselves with the simultaneous goal of development and the elimination of poverty.

Yet while many policies and programmatic interventions are promising on paper, they have proven to be ineffective, or worse, to have negative effects on the populations living in targeted conservation areas. Critiques of environmental conservation and conservation as development have highlighted the way in which populations have been forcibly displaced, and how, for example, indigenous rights have been violated. Examining state and transnational efforts to control resource exploitation highlights how the regulation of nature may introduce new social and material problems into targeted areas. In the age of increasing environmental awareness, researchers must examine not only the roots of environmental degradation but also the interventions themselves.

This article discusses how environmental degradation has been conceptualized and the initiatives that have arisen in response. I refer to environmental degradation as human instigated damage and destruction of what are commonly referred to as natural resources: water, land, trees, animals, and air. Degradation has been conceptualized in multiple ways, including neo-Malthusian explanations related to population growth, and explanations deriving from political ecology that site resource appropriation. As environmental conservation interventions sought to protect biodiversity throughout the 1980s and 1990s, governments and international NGOs were interested in melding conservation with the elusive goal of economic growth and development. This article reviews the literature on environmental degradation and the literature on development, as well as the intersection of the two. It covers trends in conservation such as parks and protected areas, the conservation and development paradigm, and neoliberal market-based environmental regulation.

Views of Environmental Degradation from Malthus to Political Ecology

Chronic degradation such as air pollution and short crisis events such as oil spills continue to galvanize local and global concern for the environment. The human effects on environmental change are so profound that a new geologic age has been proposed. The Holocene, the geologic era that has defined the past 10 000–12 000 years, has arguably given rise to a new geologic era, that of the Anthropocene (Crutzen and Stoermer, 2000; Crutzen, 2002). The fact that human action has altered the planet for the worse offers the possibility that a more enlightened humanity might alter the planet for the better, presenting a formidable sense of responsibility (Gibson-Graham and Roelvink, 2009).

In the first wave of environmentalism in the 1960s, scholars theorized this degradation as the result of population growth. Drawing on the work of Thomas Malthus, commentators considered population pressure as the cause of environmental destruction. Scholarship emerging in the late 1970s and 1980s challenged this perspective, offering contrary framings. The following sections outline environmental theories championed by neo-Malthusianism and political ecology.

Neo-Malthusianism

Post-World War II framings of environmental degradation were based on concerns of population growth and natural resource bases. This movement differed drastically from the conservation movement that Theodore Roosevelt headed in the 1890s and 1900s (Robbins, 2012). The post-War movement drew on the work of the philosopher Thomas Malthus, and focused on growing populations as the primary cause of degradation. Malthus' original writings were not immediately directed at the

environment, but rather theorized poverty. In the late eighteenth and early nineteenth centuries, Malthus saw population growth as the cause of the urban poverty he saw in England. His thesis held that it was the uncontrolled growth of the poor that was responsible for the increase in poverty. The poor, unable to restrain themselves from reproducing, would increase in number while the rich practiced measured self-restraint. Malthus' theories held that because of this, hunger and death were the forces that kept poor populations in check. For him, poverty was quite simply a condition of human existence (Rao, 1994).

In the 1960s, environmental movements drew on these theories. The association of population growth with poverty shifted to a connection between population growth and the degradation of natural resources and the environment (Peet and Watts, 1996). Population-oriented environmentalists drew on Malthus and warned about the increase in numbers of impoverished people and what this would mean for the environment. It was posited that growing populations would consume nature's assets beyond the point of self-renewal (Robbins, 2012). In his widely read book, *The Population Bomb* (1968), Paul Ehrlich raised public concern about population growth, especially in low-income countries, and pointed out the coming crisis that growing global pressure on natural resources was causing.

While this alarmist perspective lost momentum after the 1980s, the link between population growth and degradation has been maintained through the work of multiple international organizations. Multilateral institutions have continued to tie environmental degradation to population growth and therefore the need for population control and family planning. Accords such as the 1994 UN International Conference on Population and Development cemented relationships between family planning and environmental degradation (Hartmann, 2006). In the late 1990s, for example, the World Resources Institute cited population growth since 1950 as a primary actor in spurring anthropogenic degradation (Leach and Fairhead, 2000). As recently as 2013, the United States Agency for International Development (USAID) funded environment projects still assert relationships between population and the environment (USAID, 2013: 22–24).

Yet critics pointed out that environmental degradation can occur with or without population growth (Blaikie, 1985). Correlative relationships between population growth and degradation may misrepresent the relationships between people and forests (Leach and Fairhead, 2000). Concepts such as population 'carrying capacity' ignored the movement of resources and blamed those most proximate to resource extraction, ignoring detrimental consumptive practices that had tangible affects but were geographically distant. Political ecology arose as a response to these population based theories of degradation.

Political Ecology

Neo-Malthusian focus on precipitous population growth hid the realities of class divisions and inequalities of consumption that undergirded environmental degradation (Robbins, 2012). Political ecology combines concerns of power and inequality while considering questions of the environment. In doing so, political ecology refutes the population and resources view and asserts the centrality of poverty in degradation (Martinez-Alier, 1991). From the beginning of political ecology, a strong difference has been made between population pressure on resources and production pressure on resources (Blaikie and Brookfield, 1987).

Anthropologist Eric Wolf first used the term political ecology in 1972 to link land-use discussions with global political economy. The interdisciplinary field arose in the early 1980s from a combination of anthropological human ecology and Marxist-inspired world systems theory. Geographers Piers Blaikie (1981, 1985), and Harold Brookfield (Blaikie and Brookfield, 1987), famously authored the soil studies that would become the foundations of political ecology. They argued that previous studies of soil degradation had been myopic in their focus. Rather than study simply farmers, land, and soil scientists, Blaikie and Brookfield argued for analysis that included the land manager in a broader historical, political, and economic context. By using this inclusive focus, political ecologists argue that environmental degradation should be understood as a series of extractive relationships. Investigations of political ecology often highlight accumulation through dispossession, and focus on the marginalized position of rural populations. Because rural land managers may be merely negotiating the constraints of larger processes of accumulation that extract resources (crops, wood) from their lands, examinations that fail to take these perspectives into account are severely limited.

As political ecology grew, it continued to examine power and the environment, but also incorporated emerging theoretical perspectives from other social sciences. In the 1980s and 1990s, political ecology was complemented by feminist political ecology (Rocheleau et al., 2013), which analyzed gender dynamics in the environment. Others incorporated post-structuralism, arguing that nature was not a material 'given' but rather a discursive and social production (Peet and Watts, 1996). Contemporary political ecologists in the post-2000s have followed this thread, questioning assumptions about what the environment is. Many have pushed for understandings of the environment that blur the distinction between 'nature' and 'culture' paying attention to the existence of multiple world views, or ontologies (Escobar, 1999; Biersack and Greenberg, 2006; Kohn, 2013; Descola, 2005). Political ecologists not only challenge prevailing ideas about degradation, but raise questions about how degradation and the 'natural' environment is defined and addressed.

The Growth of Development and Development Aid

Since Blaikie and Brookfield's (1987) work, political ecology has focused not only on degradation but also the interventions that address that degradation. International development organizations have played a large part in such projects and initiatives. Here I refer to development as the drive for continued growth and the work done by development agencies and government actors in attempts to achieve economic growth. In a more basic sense, development is also the linear pursuit of progress that emerges with global capitalism (Leys, 1996). But as social scientist Wolfgang Sachs (1993) points

out, that very progress of industrialization comes at the cost of environmental resources. This unwitting destruction has been referred to as the second contradiction of capitalism: as capitalism and growth spreads, it needs resources in order to produce commodities for consumption. This process of growth therefore devours the very resources on which profits depend (O'Connor, 1998).

Development also refers to a set of theories that arose starting in the 1950s that address what was then deemed to be the problems in 'the third world.' The goal was to transfer Western knowledge and technology to make postcolonial countries more productive. Technical expertise wielded by Western Europe and the United States was called upon to benefit the so-called 'underdeveloped' nations. In those efforts, industrialization gained heightened importance and the so-called experts from the global north were sent to give technical expertise to the global south. Therefore, development was not only a theory of progress but also became defined by the imposition of planned social interventions (Escobar, 1995).

The results of the development paradigm and development aid have been severely critiqued on economic and social grounds. Economic development has been discussed as contributing to the improvement of the 'developed' countries at the expense of the 'underdeveloped.' Early development aid was little more than a way for previous colonial powers to benefit from the production of previous colonies (Leys, 1996). In some cases, planned social programs continued to propagate resource extraction and relocation in target countries (Greenough and Tsing, 2003).

Development aid has had profound social and discursive effects as well. Such a discourse of 'developed' and 'underdeveloped' creates blanket categories that eliminate difference and feed the needs of the development industry (Escobar, 1995). Development processes and documents construct particular needs, often quite divorced from reality (Ferguson, 1999). The constant drive and 'will to improve' justifies the work of experts (most often from the global north) and increases their control of nature (Li, 2007). Scholarship has also attempted to understand development as a particular type of practice (Mosse, 2013). Technical interventions create ideal models of development and cite expert opinion, but the realities 'on the ground' are quite different. Questions have arisen as to if good policy even matters, as the exigencies of development funding structures and the often stark disconnect between aid workers and beneficiaries create complications in moving from an ideal to a reality (Lewis, 2004).

Environmental Protection Strategies and Interventions

This section looks at how development interventions have intersected with ongoing environmental efforts. The environmental awareness of the mid-twentieth century translated into international agreements among countries in the 1980s intended to support sustainability and increase conservation (Peluso, 1993). 'Sustainability' emerged as a term highlighting the integration of development with environmental conservation. The term gained increased attention at the 1992 United Nations Conference on Environment and Development 'Earth Summit' in Rio de Janeiro (Sachs, 1993). If environmental protection was on the table, would it come at the expense of the economic growth of countries? In the end, the Rio conference held that economic development was of primary concern. It was the Brundtland Report in 1987 that cemented at Rio a simultaneous discourse of both growth and environmentalism. 'Sustainable development' would combine these ideas and become the champion phrase of the 1990s and into the 2000s.

Multilateral institutions such as the United Nations Environmental Programme, and large international NGOs such as Conservation International began to define the standards and patterns of interventions that would tackle both development and environmental conservation. USAID, the World Bank, the Department for International Development of the United Kingdom, the UN, and others contribute to goals of both development and environmental protection and conservation. These institutions plan and implement projects that aim to protect natural resources, conserve biodiversity, and achieve market-based environmental regulation.

While overt goals of environmental protection have been well publicized, the latent effects of programs and projects have often been eschewed. Two common strategies are parks and protected areas, and the conservation and development framework. In the 1990s and more fervently in the 2000s, neoliberal tactics of conservation have been developed. In each of these strategies, there are questionable patterns of engagement which have prompted the continued vigilance of scholars: "In any given conservation setting, few people may be interested in actual environmental protection, while many people may use the *idea* of protection to further other claims" (Haenn, 2005: 25).

Parks and Protected Areas

Parks and protected areas seek to protect nature and biodiversity by bounding particular spaces. They have long affected not only the environments that they seek to protect, but also the lives and communities that live in and around these areas. The number of protected areas has expanded greatly since World War II, and since the early 2000s the number has risen even more (Adams and Hutton, 2007; West and Brockington, 2006). By 2005, it was estimated that close to 12% of the land surface of the planet was covered by more than 100 000 protected areas (Chape et al., 2005). The establishment of these areas is in hopes of protecting and increasing biodiversity, yet the benefits of this extraordinary number of protected spaces has been called into question. The idea that a park or protected area preserves ecologies and communities in a state of suspended animation is assumed, but quite problematic. Rather, parks and protected areas take dynamic ecologies and societies and alter them, often radically, into a manageable and externally predetermined form (Holmes and Brockington, 2012; West and Brockington, 2006).

The widespread establishment of protected areas brought forth a wave of critiques of displacement in the late 1980s and into the 1990s. These analyses became even more sweeping and caustic in the early and mid-2000s (Agrawal and Redford, 2009). Alterations of natural and social environments have employed multiple forms of violence. Even early iterations of national parks, such as the national park system in the United

States, relied on techniques of displacement in order to achieve their goals. In fact, the US Calvary evicted long-time residents for the establishment of Yellowstone National Park (Jacoby, 2001; Holmes and Brockington, 2012). Parks and protected areas following US-derived models have followed this trend, evicting humans from spaces that will soon become 'protected.' Under this model, humans are seen (often incorrectly) as a priori threats to biodiversity (Adams and Hutton, 2007; West, 2006).

Displacement has been one of the most profound impacts of protected areas. Displacement has a direct affect on livelihoods and leads to risks of impoverishment (Brechin et al., 2002). In Kenya, 'legitimate' violence was used by the state to create protected areas with the goal of state resource sovereignty. In the end, the protected area restricted the movements of Masai nomads and validated lethal force against poachers, ignoring the context in which groups had been forced to assume alternative means of income (Peluso, 1993). Even if people are not removed from protected areas, these spaces alter land-use rights in general (West et al., 2006). While some argue for the increase in the size of protected areas and the rigor with which they are protected, these measures would likely result in even higher rates of displacement (Agrawal and Redford, 2009).

Often, resources from protected areas find their way into the hands of elites or other power brokers. Research in Guinea-Bissau showed that the benefits of conservation efforts do not always go to the 'beneficiaries' but are often controlled by the NGOs that act as intermediaries (Temudo, 2012). In effect, these areas are designed to exclude the majority of people from making decisions about an area and in practice this often translates into the maintenance of power within the hands of elites (Haenn, 2005). In Mexico, anthropologist Molly Doane (2012) found that large organizations had eschewed more local efforts. While local people were preserving land through communal control, organizations like the World Wildlife Fund redefined forests as 'rain forests,' appropriating the symbolic value of land and dismissing other efforts. Broad statistical reviews of parks and protected areas do not capture many of these dynamics, in-depth studies suggest that the extent of these negative effects may be more serious and widespread than reported.

Conservation and Development

Responding to the simultaneous calls for development and environmental protection, conservation has been intimately tied to development and poverty alleviation. The Integrated Conservation and Development Project model was fostered in 1980 by the International Union for the Conservation of Nature, the World Wildlife Fund, and the United Nations Environmental Programme (Dove, 2006). The model proliferated in the 1990s and has found global growth through commitments to raising the standards of living within protected areas (Wells, 1992).

This reworking of development toward environmentalism has prompted social science to follow with a steady and growing series of critiques (Sachs, 1993; West, 2006). Agrawal and Redford (2006) published a systematic survey of 37 projects attempting biodiversity conservation and poverty alleviation, finding little to no evidence of the synergy between the two goals. As the goals of development and poverty alleviation are applied to conservation goals, they may propagate a particular course of development that relies on natural resource exploitation, as in the Pacific region of Columbia (Escobar, 2008). However, conservation may also appropriate value from landscapes by transforming them into a type of capital that can circulate and generate further value at the global level (Garland, 2008). Conservation, through development interventions, has imposed changes on local livelihood strategies, turning 'target groups' into accessible sources of labor, for example, as workers on tea plantations in Rwanda (Masozera and Alavalapati, 2004).

Analyses have also highlighted how conservation and development imposes prefabricated definitions on the communities in question. 'Communities' are often erroneously treated as homogenous, territorially bounded, and sharing common norms and interests (Temudo, 2012). Often, this is the result of a 'rendering technical' that glazes over complex political and social realities in favor of technical solutions conceived of by aid institutions, states, and policy makers (Li, 2007). This rendering technical strips local areas of complexity and difference, relying on the assumption that local inhabitants are threats to resources (West, 2006). Often, these definitions produce myopic visions, ignoring evidence outside the area in question. For example, project documents in a cross-border park targeted the water-wasting practices of Lesotho agriculturalists, yet remained silent about the consumption of water in luxurious golf courses nearby (Büscher, 2012).

Much of the concern about conservation and development overlaps with the ways in which the market economy has been imposed on the environment. The very premise of conservation as development ties conservation to development, and the environment to the market economy (West, 2006; Escobar, 1999; Sachs, 1993).

Market Regulation and REDD+

Increasingly, markets are being used to regulate the environment, and as a response, political ecologists including geographers, anthropologists, and sociologists, are examining the results of neoliberal environmental regulation. Neoliberal approaches assert that "human well-being can best be advanced by liberating individual entrepreneurial freedoms and skills within an institutional framework characterized by strong private property rights, free markets and free trade" (Harvey, 2005: 2). Turning toward the dynamics of the market, these strategies seek to commodify environmental goals and often, the environment itself. Through market mechanisms the monetization of the environment will then ideally bring forth the 'rational economic actor.' It is hoped that this monetization will alter behaviors toward economic gain and away from economic loss.

While neoliberal economic policies ostensibly espouse market deregulation, evidence suggests that in fact neoliberalism entails 'reregulation' as well: government regulation is used to transform previously untradable things into tradable commodities (Igoe and Brockington, 2007). Many conservation interventions are designed on the assumption that the biggest obstacle to effective conservation is that nature has not

yet been adequately commodified (McAfee, 1999; Grandia, 2007). A key component of turning nature into buyable and sellable forms is the demarcation of territories in which this can occur. The demarcation and capture of resources not only affects individuals living in proximity, but also puts control in the hands of external agencies and institutions such as large international NGOs. Many of the indigenous groups affected by neoliberal conservation have therefore been on the losing side, finding their livelihood strategies criminalized by newly demarcated zones (Brockington and Igoe, 2006).

One such neoliberal environmental strategy has been carbon markets. Carbon offsets were developed as 'tools to manage anthropogenic climate change' by trading tons of carbon dioxide in international markets (Bumpus, 2011: 612). In effect, carbon credits are purchased by investment in carbon reduction projects, reductions that would not have occurred if the project had not taken place (Yamin, 2005).

Political ecologists have argued that the development of forest carbon networks has amplified existing exclusions (Filer and Wood, 2012). While carbon offsets may espouse market regulation of environmental contamination, the commodification of carbon markets has been critiqued for veiling problems of displacement and continued environmental degradation. By following a Dutch energy firm's carbon trade, Checker (2009) demonstrated the intricate way in which the company purchased carbon offsets to hide detrimental coal mining ventures in the United States, while simultaneously supporting a protected area in Uganda accused of propagating violence and displacement. A veneer of progress hid human rights violations in the form of displacement and allowed for ongoing extractive processes to be obscured behind supposedly proenvironmental efforts.

The REDD+ programme is a specific example of the carbon regulation markets. REDD+ (Reducing Emissions from Deforestation and forest Degradation; the '+' stands for protecting biodiversity and local livelihoods) aims to reduce carbon emissions caused by the cutting of forests. In 2007, the Subsidiary Body for Scientific and Technical Advice of the United Nations Framework Convention on Climate Change unveiled the concepts of REDD+. Broadly, REDD+ is a framework for the measurement and exchange of carbon stock, one that seeks to preserve forested space in developing countries by estimating carbon (tons per territory) and creating a market for that carbon among various actors abroad. While there is no single entity in charge of REDD+, several UN organizations and the World Bank are major actors (Thompson et al., 2011). One of the most serious critiques has been that REDD+ programs ignore people's relationships with the forest in favor of state and international accords. Some argue that REDD+'s efforts are toward building government capacity. However these efforts are often far from the interests of marginalized and indigenous peoples, and may exacerbate existing inequalities (Agrawal, 2010). While indigenous participation is facilitated by UN-REDD administrative structures, this participation has been critiqued for legitimizing the top-down project model without the meaningful consideration of stakeholders. Because the structure revolves around carbon accounting, there are opportunities for more heavily centralized forest management activities, activities that are not designed to incorporate more organic types of participation (Börner et al., 2010; Phelps et al., 2010).

While the REDD+ initiative envisions positive outputs to landowners in the area, these benefits may be problematic, unequitably rewarding larger landholders more than smaller landholders, and presenting far more challenges to lower-income families who practice, for example, swidden (shifting cultivation) agriculture on small plots (Börner et al., 2010). Similar to critiques of conservation more generally, Whiteman et al. (2010) argue that this type of framework continually privileges elites in developing countries. In doing so, it validates particular perspectives while marginalizing others. Böhm et al. (2012) argue that in practice, carbon markets are new creative modes of accumulation and are unlikely to transform dynamics in ways that form a more sustainable global economy and help the rural poor.

Alternative Visions of Conservation

Given the questionable results of top-down environmental and development interventions, other models of conservation have been proposed that incorporate the above critiques. Participatory conservation interventions have arisen that attempt to add more meaningful involvement of project beneficiaries. While broader goals take time, and participatory methods still need to consider the social dynamics within target groups, participatory interventions can bring about new types of conservation awareness (Khadka and Nepal, 2010). Research in the past year points to ways that participatory conservation might move away from 'quota'-based participation to develop more inclusive forms of incorporating marginalized groups (Dahal et al., 2014). Scholars focusing on participation note that community based models do not directly influence the degree of participation, and emphasize that an awareness of the local context is a far more important variable for future interventions to consider (Méndez-López et al., 2014). In one case in Mexico, participation was best achieved when NGOs were removed, allowing space for other types of groups to care for natural resources outside of the existing development paradigm (Martinez-Reyes, 2014).

As recommended by West and Brockington (2006), planners would be well served to recognize alternative understandings of the environment. Similarly, alternative visions of development, espoused by those living in the areas in question, might be taken into account (see Escobar, 2008). Interdisciplinary teams are arguing for more 'local' studies that embrace the knowledge produced by social scientists and critics (Gardner et al., 2013). The ongoing contemporary work of political ecologists and other scholars is to not only continually document and understand environmental degradation and interventions, but to document potential ways in which care for natural resources might occur.

Environmental Determinism

Innes M Keighren, Royal Holloway, University of London, Egham, UK

Abstract

The doctrine of environmental determinism has, for more than two millennia, been used to explain the social organization and physical characteristics of populations. Classical scholars deployed humorism to define a causal relationship between environment and temperament, physiognomy, and intelligence. Enlightenment philosophers used environmental explanations to classify human variation and progress. During the nineteenth century, environmental theories were combined with biological metaphors of development to establish hierarchies of racial difference and to justify imperialism. Environmental determinism was central to the emergence of disciplinary geography and anthropology in the nineteenth century, but was subsequently subject to censure and rejection as a pseudoscience.

Environmental determinism, in its simplest expression, is a principle which states that human activity, culture, and physical and mental characteristics are, at once, informed and inhibited by the geographical and climatic conditions of the physical environment. As a causal mechanism used to describe and explain human development, and the qualities, successes, and failures of individual populations, environmental determinism has a venerable yet contested history. For more than two millennia the concept that geography matters to human affairs has been deployed for a variety of ideological purposes: to describe the geography of morality, to justify imperial processes of colonization, and to construct race as a scientific category.

The intellectual currency of environmental determinism in a variety of disciplinary contexts has varied, however, in relation to perceptions of its explanatory value and pejorative social and political implications. From being an intrinsic component of interpretative work in geography and social anthropology in the late nineteenth and early twentieth centuries, environmental determinism has become passé, even taboo. Notwithstanding the significance to, and validity of, environmental explanations in archaeology, paleontology, and allied disciplines, recent attempts by journalists and popular science writers to reappraise the significance of geographical and climatic influences on human societies have been subject to robust censure by scholars in the humanities and social sciences who regard such work as pseudoscientific at best, and racist at worst (Erickson, 1999; Judkins et al., 2008; Livingstone, 2012; Sluyter, 2003). To understand the vociferousness of contemporary criticism of neoenvironmental determinism, it is necessary to appreciate the concept's historical development and varied expression.

Classical Origins of Environmental Determinism

Environmental determinism, as a philosophy of natural law, has a prehistory which can be traced through the mythologies and theologies of a variety of ancient cultures and religions, not least those of Mesopotamia, the Indus Valley, and what is now China (Glacken, 1967). Philosophical and religious reflection on the role of the physical environment in shaping human culture and civilization has, in a variety of contexts, been central to understandings of societal growth and decline, material cause-and-effect relationships, and the divine (or otherwise) order of nature. The genealogy of environmental determinism in European thought can be traced to the historical, chorographical, and medical discourses of a variety of ancient Greek and Roman scholars who attempted to place understandings of the causal effects of the environment on a rational basis. Among these classical antecedents, Hippocrates of Cos (*c*.460–377 BC), Aristotle (384–322 BC), and Strabo of Amaseia (*c*.63 BC–AD 23) are common ancestors of later deterministic philosophy.

The physiological basis to environmental influence was articulated in its earliest form in a treatise on disease – *On airs, waters, and places* – which constituted part of a collection of medical scholarship (the *Corpus Hippocraticum*) attributed, at least in part, to Hippocrates (Jouanna, 1999). Most probably written to assist itinerant physicians in the correct diagnosis of the diseases they were likely to encounter in different geographical locations, *On airs, waters, and places* was based upon an elemental understanding of the natural world and on the differing effects of earth, air, fire, and water (and their corresponding characteristics: cold, dry, hot, and wet) on the human body. The treatise proposed that an individual's health – and, consequently, personality and physique – was determined by the physical environment's influence upon their bodily humors: the four fluids (blood, yellow bile, black bile, and phlegm) that serve to regulate mood, temperament, and physical well-being. Health was maintained by an equilibrium of the humors; disease promoted by their disequilibrium.

Combined with the persistent influence of climate, topography, soil, and water, humorism was deployed to explain variations in the physiology and mental and moral character not simply of different individuals, but of different populations. The relative superiority or inferiority of populations could thus be explained by reference to the favorable or detrimental characteristics of their physical setting (Wear, 2008). The Hippocratic formulation of environmental influence cast a long shadow across European understandings of human social and physical development and, in one modified form or another, was employed as the self-evident basis to subsequent discourses on law, politics, civilization, and race (among other

topics). The ideological potential (and consequence) of an environmental explanation of human development was evident in Greek scholars' attempts to understand the comparative success of their own civilization.

For Aristotle, the achievements and superiority of the Greek civilization were explained, in large part, by a favorable geographical location and a temperate climate: a 'golden mean' between the too-cold north and the too-hot south (Glacken, 1967: p. 93). In Aristotle's (2013: p. 199) flattering formulation, representing a Mediterranean-centered worldview, Greece was the geographical intermediate between unfavorable climatic binaries:

> The nations in cold locations, particularly in [northern] Europe, are filled with spiritedness, but relatively lacking in thought and art; hence they remain freer, but lack political governance and are incapable of ruling their neighbours. Those in Asia, on the other hand, have souls endowed with thought and art, but are lacking in spiritedness; hence they remain ruled and enslaved. But the stock of the Greeks shares in both – just as it holds the middle in terms of location. For it is both spirited and endowed with thought, and hence both remains free and governs itself in the best manner and at the same time is capable of ruling all, should it obtain a single regime.

Aristotle's interpretation in his *Politics* of Greek success thus served to define the moral boundaries of civilization and barbarism; a demarcation that would subsequently exert a long-standing influence on European conceptions of the association between climate, race, and intellectual capacity.

The relationship between geography and the state was later developed, and further refined, by Strabo in his historical-cultural account of the Roman Empire under Augustus. While Strabo attributed the success and influence of the Empire in part to the peninsular character of Italy (which secured it against attacks), the quality of its natural harbors (which facilitated trade and commerce), and its varied and temperate climate (which offered favorable conditions for agriculture and animal husbandry), he also emphasized the important role of human agency in shaping societal characteristics. In rejecting a straightforwardly climatic account, Strabo argued that social "institutions and education" served to shape "Arts, forms of government, and modes of life" irrespective of the climatic context in which they occurred (Strabo, 1854: p. 155). For Strabo, the physical environment was an explanatory (rather than a deterministic) mechanism to account for the development of culture, states, and their institutions. The differing significance attributed to geography by Strabo, Aristotle, and scholars in the Hippocratic tradition served, in certain respects, to define the lineaments of subsequent debate on environmental causation and determinism and on providence and free will.

Climate, Politics, and Human Types: Environmental Determinism from Magnus to Montesquieu

While the theological cosmology of the Christian church did much to constrain scholarly speculation in Europe during the Middle Ages on the relationship between the natural environment and human culture, echoes of classical understandings of climatic and geographical influence were nevertheless evident in, and often implicit to, the work of various medieval theologians and scholars. Writing in the seventh century, for example, Isidorus Hispalensis (*c.*560–636), archbishop of Seville, attributed the physiology, physiognomy, and character of different populations to their environmental setting: in his formulation, Romans were stately, Greeks shifty, Africans sneaky, and Gauls warlike (Friedman, 2000: p. 42). A tacit assumption as to the modifying influence of the physical environment was apparent, moreover, in the writings of Otto of Freising (*c.*1114–58), bishop and historian, who, in chronicling the invasion of northern Italy by the Lombards during the sixth century, noted that the raiders "gave up their wild customs and adopted Italian ways, partly because they married native women but partly as a result of the nature of the country and climate" (Wright, 1965: p. 232). A similar concern with climatic influence was evident in the work of the Dominican scholar Albertus Magnus (*c.*1200–80) who examined, in his treatise *De natura locorum* (On the nature of places), the causal relationship between the globe's climatic zones and the appearance, skin color, and temperament of their inhabitants.

In certain respects, philosophical reflection on environmental influence reached a particular epitome in the work of the French jurist and political theorist, Jean Bodin (*c.*1530–96). In seeking to provide a rational account of the relationship between history, geography, and the contours of contemporary society (with a view to identifying the system of law and sovereignty most suited to specific nations), Bodin synthesized the environmental theories of classical scholars and medieval theologians. Bodin sought in his wide-ranging text – *Six livres de la république* (The six books of the commonwealth, 1576) – to demonstrate that the earth *directed* the theater of human life. Bodin combined humorism with geographical and astrological explanations to account for human character and actions. Like Albertus Magnus, Bodin took as self-evident the existence of global climatic regions (frigid, temperate, and torrid zones) which, through humoral mechanisms, exerted specific influence on the physical and mental characteristics of those regions' inhabitants.

Bodin looked, moreover, beyond the terrestrial environment to assess the influence of the celestial realm upon society, culture, and individual disposition. To Bodin, the inhabitants of the southern parts of the globe, governed by Saturn, were, for example, predisposed to religious contemplation, while their northern counterparts, ruled over by Mars, were warlike. With strong echoes of the golden mean identified by Aristotle in his *Politics*, Bodin contended that the people of the intermediate latitudes – subject to the influence of Jupiter – were of even temperament, combined the most favorable characteristics of northern and southern populations, and were (by virtue of their geographical situation) inclined to rule over others. While Bodin considered environmental and astrological influences to be persistent, even inexorable, he, like Strabo, nevertheless allowed for the possibility that they could be resisted through determined and conscious social effort.

Bodin's deterministic philosophy had a variety of inheritors, not least the French political philosopher Montesquieu (1689–1755) – arguably the Enlightenment's most influential

proponent of environmental causation. Montesquieu's principal intellectual ambition – outlined in his treatise *L'esprit des lois* (The spirit of laws, 1748) – was to develop a rigorous framework by which human behavior could be explained by reference to morals, customs, and laws as well as to environmental context. From a systematic analysis of empirical data on the environmental and social characteristics of different populations and geographical locations – furnished, in part, by the Enlightenment's burgeoning travel literature – Montesquieu advanced a multicausal explanation which distinguished between environmental and cultural influences on human organization. Montesquieu drew attention, in so doing, to the 'internal (social and psychological)' and 'external (biophysical and technological)' milieux in which human life was enacted and by which it was shaped (Buttimer, 1971: p. 12).

Montesquieu's analysis was, in this respect, more nuanced than was that of Bodin, but he nevertheless considered the physical environment, and climate specifically, to be 'the first and most powerful' of explanatory mechanisms (Withers, 2007: p. 140). While the basic tenets of Montesquieu's theory were not new, his contribution to understandings of human society made it possible for Enlightenment scholars to see human progress as a fact of geography, not simply a question of history. Understood as a function of climate and of geographical situation, the assumed progression of human populations from savage and barbarous states, to commercial and polite (as they would later be categorized by Adam Ferguson (1723–1816)), could thus be seen, at each stage of development, contemporaneously in different locations on the terrestrial globe. Montesquieu's work thus exerted, in a variety of modified forms, an important influence on Enlightenment understandings of progress and of the assumed nature of human difference (Livingstone, 2011).

The Enlightenment concern with human difference and development reflected not only that era's classificatory impulse – the desire to impose order and regularity on the dizzying variety of the natural world – but also a more elemental interest in human origins. Quite apart from the physical and social mechanisms which might explain human difference, there was significant debate as to whether the indices by which that difference might be measured (skin color, stature, skeletal form, hirsuteness, among others) were innate characteristics or superfluous by-products (Hudson, 1996). In his *Systema naturae* (The system of nature, 1735), for example, Carl Linnaeus (1707–78) described a fourfold classification of human types based upon their continental distribution and skin color: white Europeans, red Americans, yellow Asians, and black Africans. While Linnaeus and many eighteenth-century theorists of race regarded these categories as fixed, bound to classical understandings of the humors and to defined geoclimatic zones, others, such as Buffon (1707–88), saw human difference as a rather more variable and dynamic phenomenon: the consequence of biological lineage and movement across space, as well as climatic influence.

For Buffon, who believed that all human populations shared a common (European) origin, dissimilarities were to be explained by the persistent influence of different climatic regimes. The relative superiority or inferiority of individual groups was not, then, the consequence of inherent qualities, but of the capacity of the environment to 'degrade' or 'elevate' those populations in moral and physical terms. A population's traits, both desirable and disagreeable, could be gained and lost under the influence of differing climatic contexts: Linnaean categories were not fixed, but mutable. Buffon's revision to Linnaeus's scheme notwithstanding, climatic understandings of human variation – developed further by Immanuel Kant (1724–1804), Johann Friedrich Blumenbach (1752–1840), among others – served to define a hierarchy of human types based upon the favorable (or otherwise) qualities of their specific geoclimatic situation, which always defined Europeans as its epitome. Although climatic explanations of human variety were not universally agreed upon by Enlightenment scholars – Voltaire (1694–1778), Henry Home (1696–1782), and David Hume (1711–76) were each critical in different ways of Montesquieu's attention to environmental influence – they were nevertheless central to marking out the contemporary globe's moral geography and to attempts during the nineteenth century to interpret race as a scientific category (Jackson and Weidman, 2004).

Biological Metaphors and Evolutionary Mechanisms in Environmental Determinism

Enlightenment-era debate concerned with human difference and progress was, at base, defined by the relative significance attributed to the social and the environmental as explanatory factors. While the interactions of populations and their environment had been considered at various stages during the eighteenth century as a reciprocal phenomenon (i.e., that humans has the capacity to modify their physical environment through processes of agriculture, deforestation, and so on), it was not until the nineteenth that this coconstitutive relationship was addressed systematically. It was done so, in part, by the Prussian naturalist and traveler Alexander von Humboldt (1769–1859). A five-year exploration of topical America between 1799 and 1804 served as the empirical foundation to Humboldt's philosophy of unity in nature; an approach which sought to describe the interrelatedness and codependence of natural and cultural phenomena through the biological metaphor of the organism.

Like earlier contributors to debates on environmental influence, Humboldt attributed significance to climatic zones (albeit defined in a more systematic manner than Magnus and Bodin were capable of). Humboldt's was, however, not a deterministic interpretation. Articulated most fully in his five-volume magnum opus *Kosmos* (published between 1845 and 1862), Humboldt viewed environmental factors as influences on human life rather than as determinants of it:

> Dependent, although in a lesser degree than plants and animals, on the soil, and on the meteorological processes of the atmosphere with which he is surrounded – escaping more readily the control of natural forces, by activity of mind and the advance of intellectual cultivation, no less than by his wonderful capacity of adapting himself to all climates – man everywhere becomes most essentially associated with terrestrial life.
>
> Humboldt, 1849: p. 360–361

In Humboldt's ecological rendering, the physical environment was not a yoke under which human populations labored,

but was the means by which they were nurtured and thus a resource to be revered and protected. Together with his near contemporary, Carl Ritter (1779–1859), Humboldt did much to place the study of human–environment relations on a systematic basis (Martin, 2005).

Humboldt's organismic understanding was further refined by the theories of biological evolution advanced by Jean-Baptiste Lamarck (1744–1829) and Charles Darwin (1809–82). While Lamarck and Darwin proposed distinct mechanisms to explain evolutionary change in species – and held dissimilar views as to progress, direction, and order in respect to that change – each attributed direct significance to environmental and climatic factors in accounting for transmutation. In simple terms, Lamarck ascribed evolutionary change to the inheritance of characteristics (i.e., adaptations to the environment) acquired during the lifetime of the individual organism. Darwin, meanwhile, understood evolution to be a rather slower, more stochastic process whereby random mutations might confer on the organism an advantage in dealing with its environmental context. Those advantages would increase the survival and reproductive success of the individual, and be passed on to the following generations more often than would less-favorable characteristics.

In various modified forms, the ideas of Lamarck and Darwin were applied, most particularly through the work of Herbert Spencer (1820–1903), to further develop understandings of human social and cultural evolution in relation to environmental circumstances. Spencer's characterization of natural selection as 'the survival of the fittest' encouraged further attention among scholars to questions of environmental causation, often with pejorative consequences. Social Darwinism, as Spencer's reading of evolutionary theory was characterized, was used, variously, to support laissez-faire economics, to justify imperialism, to define hierarchies of racial superiority, and to validate eugenics (Hawkins, 1997). While the tenets of Social Darwinism were not fundamentally dissimilar from those of previous theories of environmental causation, the application of what were assumed to be scientific principles to its investigation meant that its influence across geography, anthropology, zoology, and medicine, among other disciplines, was considerable (Livingstone, 2012; Peet, 1985).

Environmental Determinism and the Academy: From Humboldt to Huntington

The construction, during the late nineteenth century, of human evolution as a question of geographical and environmental determinants was central to the development of academic geography as the study of the causal relationships between organic and inorganic phenomena. Although many European geographers (or protogeographers) regarded the systematic elucidation of cultural–environmental relationships to be the discipline's scientific raison d'être, there was nevertheless considerable disagreement (reflecting Montesquieu's long-standing society–milieu distinction) regarding the relative significance attributed to social processes and to environmental contexts in explaining human character and change. This debate was characterized by an oppositional binary between deterministic explanations (associated with work of Friedrich Ratzel (1844–1904) and Ellen Churchill Semple (1863–1932), among others) and possibilistic interpretations (advanced, among others, by Paul Vidal de la Blache (1845–1918) and Carl Sauer (1889–1975)).

Drawing inspiration from the work of Oscar Peschel (1826–75) and Ferdinand von Richthofen (1833–1905) on the comparative study of landforms, and from Moritz Wagner (1813–87) on migration and organic diversity, Ratzel sought to put the study of human geography (*anthropogeographie*) on a scientific basis through a systematic analysis of the biotic and cultural features of different social groups in relation to their environments. For Ratzel, civilization was the product and consequence of the interrelationship of culture and environment, not a separate and independently arrived-at phenomenon. In this respect, Ratzel saw the evolution of human societies to depend upon a Spencerian struggle for survival, with those populations most adept at responding to the challenges and opportunities of their environmental circumstances being ultimately successful. Ratzel employed the concept of living space (*Lebensraum*) in describing an organismic model of human society that developed "within a frame (*Rahmen*), exploiting a place (*Stelle*), needing space (*Raum*) and finding limits (*Grenzen*)" (Wanklyn, 1961: p. 23). Ratzel's manifesto met with a varied response among contemporary scholars and engendered both deterministic and possibilistic readings of the environment's likely influence on society. Ratzel's concept of *Lebensraum* – which tied the health and success of a population to the size and quality of its habitat – was later adapted and distorted in Germany, under the banner of *geopolitik*, by the National Socialist Party in support of Nazi spatial ideology (Abrahamsson, 2013; Smith, 1980).

The transmission of Ratzel's theory of environmental influence to the Anglophone world was facilitated, in large measure, by his principal acolyte, the American geographer Ellen Churchill Semple. For Semple, the central appeal of Ratzel's model lay in its potential to define the academic legitimacy of geography – to transform it from an idiographic discipline (focused on the description of specific instances and phenomena) to a generalizing, nomothetic science, one capable of defining natural laws and rules. Where Ratzel had been subject to criticism for the inadequate empirical basis to his model, Semple supplemented her interpretation of it – published in 1911 as *Influences of geographic environment on the basis of Ratzel's system of anthropo-geography* – with more than 1000 citations of classical authorities and contemporary scholarship. In this respect, Semple was more systematic in her evidential support than was Ratzel and, in so being, presented an exhaustive range of environmental explanations to account for almost every conceivable aspect of human form, character, and social organization – from religion and architecture, to economic system and moral character (Cresswell, 2013; Keighren, 2010).

Notwithstanding the range of geographical influences which Semple invoked, her stated (although arguably unsuccessful) aim was to deny a straightforwardly deterministic relationship between the natural environment and human social and physiological organization. While her prefatory remarks made this ambition clear – "the writer speaks of geographic factors and influences, shuns the word geographic determinant, and speaks with extreme caution of geographic

control" – it is evident that for many contemporary and later readers, Semple's philosophy was interpreted quite differently and regarded as the epitome of environmental determinism (Semple, 1911: p. vii). Where Semple did distinguish herself from earlier scholars of environmental causation was, however, in her treatment of human different. Semple was disinclined (at least superficially so) to use race as an explanatory category. Semple's argument was that if peoples of different ethnic stock (a term she used to encompass a population's inherited traits), who were exposed to similar environmental circumstances, were seen to display similar social characteristics, these similarities were self-evidently the consequence of environmental influence and not of inherent racial differences. Semple's opinion, like that of Montesquieu and Buffon, was that environmental circumstances were ineluctably the determinant of human difference and thus had the potential to elevate or to degrade populations irrespective of their 'stock.' While Semple proceeded with caution in her discussion of race, several of her contemporaries in Anglophone geography were less circumspect.

The work of Ellsworth Huntington (1876–1947) and Thomas Griffith Taylor (1880–1963) is representative of a trend in Anglophone geography in the first half of the twentieth century to link, on an empirical and quantitative basis, climate, race, and the development of human civilization. Whilst there was little in such arguments to distinguish them, in a fundamental sense, from those of Bodin and his inheritors, what Huntington and Taylor attempted to do differently was to place such interpretations of human-environment relationships on a statistical and apparently objective basis. Huntington and Taylor each collected vast quantities of climatic and anthropological data in developing their understandings of the links between climate (which they regarded as the primary determinant) and human intelligence, physical appearance, and moral potential. In texts such as *The Character of Races* (Huntington, 1924) and *Environment and Race* (Taylor, 1927), laid the foundation to a positivistic and scientific construction of racial categories which – although subject to censure by contemporaries such as the sociologist Franz Boas (1858–1942) – retained currency throughout much of the first half of the twentieth century and was only permanently gainsaid as a consequence of developments in the science of genetics (Hannaford, 1996).

Environmental Determinism Redux?

For geographers, social anthropologists, and other scholars of the social sciences and humanities, environmental explanations for human difference and development were, by the middle decades of the twentieth century, largely considered to be obsolete – symbolic of scientific racism and profoundly tarnished by their deployment in support of Nazi geopolitics. Nevertheless, the doctrine of environmentalism (in its deterministic and possibilistic stripes) was never entirely eliminated and has found continued explanatory validity in biological anthropology and archaeology while also exerting a certain commonsensical appeal to those social scientists for whom the wholesale rejection of environmental explanations during the second half of the twentieth century was akin to throwing out the baby with the bathwater (Merrett, 2003).

Recent contributions to neoenvironmental determinism – such as Jared Diamond's *Guns, Germs, and Steel* (1997) and *Collapse* (2005), and Robert Kaplan's *The Revenge of Geography* (2012) – have sought to draw attention to the explanatory significance of geography and of climate in accounting for human populations' relative successes and failures. For their critics, Diamond and Kaplan are guilty of uncritically repackaging deterministic philosophy – reinvigorating ideas that previously were used to construct hierarchies of human difference and to justify damaging political ideologies – and of failing to "break free … from an environmental determinist straightjacket that sees geography as nothing more than a three-dimensional physical manifestation" (Johnston, 2013: p. 3). What such criticisms reveal is quite how polarizing environmental explanations (rendered toxic by their earlier socially and scientifically dubious iterations) remain for geographers, among others. Rather than heralding a revivified debate, the response to Diamond and Kaplan suggests that existing positions are being retrenched.

Environmental Economics

Vincent K Smith, Arizona State University, Tempe, AZ, USA

Abstract

This article describes the field of environmental economics. It outlines the conceptual problems posed by environmental externalities and public goods and describes how policy addresses them. The logic of benefit–cost analysis and its role in evaluating environmental regulations are discussed. The newest methods of quasi-experimental methods for estimating the effects of rules are summarized. The distributional effects of environmental change are also discussed along with a brief summary of the challenges in maintaining economic growth while assuring that environmental quality is maintained.

Environmental economics studies the effects that environmental systems have on the positive predictions and normative recommendations of economic models (see Solow, 1991; Arrow et al., 1995). Early in the history of economic modeling, Hotelling (1931) recognized the importance of intertemporal issues for economic choices involving renewable and nonrenewable natural resources. Nearly 50 years later, Dasgupta and Heal (1979) and numerous other economists (see Smith, 2012, for a review of the new economic research on fisheries) have extended this research. Today, there is extensive theoretical and empirical literature on these topics that are treated separately in the *Encyclopedia*.

Environmental economics assumes there are things people care about, either directly because they enhance individual well-being or indirectly because they influence the production of other commodities, that are (1) scarce; (2) available outside markets; and (3) influenced by the activities of others. These objects of environmental choice (OECs) have diverse characteristics and result from a variety of activities. Seven topic areas organize this overview: the allocation problems they pose, the design of policy, traditional and new approaches for measuring trade-offs that people would make to enhance environmental amenities, OECs as risks, the distributional implications of environmental changes, and interactions between growth and environmental resources.

Problems – Public Goods, Externalities, and Congestion

Pure public goods are nonrival and nonexcludable in consumption (Cornes and Sandler, 1996; Phaneuf and Requate, forthcoming). Each person's consumption of a public good does not reduce the amount available to others. Moreover, access to these goods cannot be limited. While it is difficult to provide examples satisfying these ideal conditions, it is easy to cite examples of goods and services with attributes close to a pure public good's features. Local air quality, measured in terms of the concentration of airborne pollutants, varies with location but within large areas it is approximately the same for all individuals living there. The global concentrations of greenhouse gases (e.g., CO_2, methane, etc.) can be described as examples of pure public 'bads' because emissions of them at any location have equivalent effects on their atmospheric stocks. However, the consequences of those accumulations for climate change and local weather conditions will depend on where people live. Perfect adherence to the ideal definition of a public good is not essential to consider the implications of 'publicness' for the efficiency of different resource allocation mechanisms.

Externalities correspond to specific types of interactions between two or more economic agents. One group's (or individual's) consumption, production, or exchange activities have unintended effects on the production or consumption of others. These external effects resemble public goods (or bads) in that they can have the same nonrival and nonexcludable attributes.

Congestion describes a phenomenon whose externality effects reduce the nonrival attributes of a public good. For example, over some levels of recreational use of a beach or a wilderness area (and the levels will be different in each case) further users can be supported without extra cost or diminution in the satisfaction each person realizes from his or her use. However, at some point, this simultaneous use diminishes each person's experience. The phenomenon linking those losses to the added users of a resource at the same time is described as congestion. While all three of these concepts are relevant outside environmental applications, they have found special meaning when environmental resources provide the services treated as OECs.

These concepts are important for at least two reasons. First, the incentives created by private markets do not assure that resources will be allocated to their highest valued uses when one or more of these problems is involved. Second, the information available from markets cannot be assured to signal and evaluate the performance of economic institutions. Much of environmental economics has been developed to address these issues.

Policies – Context, Design, and Performance

Economic analysis focuses on the incentive properties of each decision context. In the case of environmental problems these details can matter to the insights offered by economic analysis. For example, economic descriptions of production and consumption activities must be consistent with materials and energy balances (Kneese and Bower, 1968). When they are not,

 http://dx.doi.org/10.1016/B978-0-08-097086-8.71038-5

it is easy to overlook the residuals and the problems that must be faced in disposing them. This insight is important because most externalities arise from using the services of an environmental asset (i.e., the ambient atmosphere or a free flowing river) for residual disposal. The form and severity of environmental externalities depend on both the types of residuals involved and the functions of the ecosystem receiving them. Many ecosystems are available with unregulated access similar to an open access resource. At some levels of use, their services may well also be subject to depletion over time.

Economic prescriptions for reducing negative externalities (as well as for congestion) focus on creating the 'right' incentives. Private choices should reflect their full or social incremental cost (i.e., the private marginal cost of producing any commodity plus the marginal external costs due to any damages associated with a commodity's production, consumption, and ultimate disposal). When the marginal damages associated with the production or consumption of a good are measured per unit of each residual emitted, it is sometimes described as the price that should be charged for that emission. Pigouvian taxes or effluent charges set equal to these marginal damages are one type of policy response to externalities.

Under simplified conditions, efficient resource allocation in the presence of environmental externalities (or congestion) requires that, at the margin, agents face the full incremental cost (or incremental benefit) of their actions including the damages caused directly or indirectly from each choice. Those experiencing damages are assumed to take defensive actions, and costs are computed recognizing these choices, but the injured parties do not need to be compensated (Baumol and Oates, 1988; Phaneuf and Requate, forthcoming).

With full information, policy can take a variety of forms. These can be charges per equivalent unit of impact (taking account of the ecosystem) to the agents causing externalities; permits to emit pollution that can be traded; and even subsidies to abate emissions. Each of these policy measures can be made to appear equivalent in terms of the incentives for incremental choices. Each approach requires different implementation rules and a different set of adjustments to reflect their effects at the extensive margin of choice (e.g., the entry and exit decisions of firms). Charges vs subsidies will affect incentives to enter an industry (Carlton and Loury, 1980; Goulder and Parry, 2008). Tradable emission permits must be denominated in units reflecting the effects of emissions on the services associated with ambient environmental quality that defines the OECs. They must also consider the initial distributions of permits among firms, the rules for trading, and their ability to be saved (if temporal patterns of emissions are important) (Tietenberg, 2006). Interactions between pollutants when they are dispersed in environmental media can interfere with the performance of permit systems designed to respond to a single pollutant under specific conditions (Evans and Woodward, 2013).

Unfortunately, in the setting where actual decisions must take place, information is scarce and uncertainty abounds. If uncertainty affects the marginal control costs, then it can affect the preferred policy instrument. Comparing charges vs marketable permits (denominated in units of the OEC), Weitzman (1974) has shown that the choice depends on the relative steepness of the marginal benefit and cost schedules. Tradable permits are favored if the marginal benefit function is steeper than marginal abatement cost and effluent charges for the reverse. His results depend on the approximate linearity of these schedules. Moreover, the conclusion is a relative statement, not an absolute judgment. Composite strategies using price and quantity instruments together can be shown to be better in the sense that they enhance overall welfare (Roberts and Spence, 1976; Pindyck, 2007).

With perfect information either instrument can, in principle, lead to an efficient resource allocation. Charging for emissions or distributing permits to pollute seems to convey 'rights' to different economic agents to use ecosystems' services. The conclusion that they can be equivalent may seem counterintuitive. While surprising, it is one reflection of the general implications of the Coase (1960) theorem. That is, in a world of perfect information, no transaction costs and no income effects (from assigning rights to ecosystem services), the theorem implies that the assignment of rights will not affect the efficient outcome. It is often used in arguments that externalities can be resolved without public sector intervention by assigning property rights to ecosystem services. In most cases, the practical relevance of this conclusion is an empirical question. Nonetheless, the economic logic underlying the theorem also explains why the available policy instruments can be equivalent.

Environmental policy in the US is the result of rule making that translates the broad goals of environmental legislation into regulations. Prior to the 1990 Clean Air Act Amendments (CAAA), rules favored command-and-control (CAC) regulations. Specific technologies were prescribed to meet objectives such as using the best available control technology to establish the lowest emission rate. These types of engineering standards specified, at the unit process level, emission rates for the same pollutant that could turn out to be different at different stages of production in the same plant. The result was very different incremental costs for controlling the same pollutants even within a single facility. Abatement costs have been increasing over time as more stringent controls were imposed. Areas found to be in nonattainment with environmental standards faced restrictions on further economic activity. The result was a policy environment seeking some ways of increasing the flexibility in how firms could respond. The 1990 CAAA changed the US regulatory climate. It offered the first large-scale emission permit trading system as a way of realizing more stringent controls for sulfur dioxide. Ellerman et al. (2000) estimate that emission trading yielded cost savings by 33–67% of the most reasonable CAC alternative. Permit trading schemes have been used in small regional markets for an array of environmental resources – including air and water pollutants, wetlands, habitat for endangered species, and carbon dioxide (see Tietenberg, 2006; Evans and Woodward, 2013).

The socially efficient consequences, considering both the private costs and the external effects of production and consumptions, of most market goods and services cannot be analyzed without recognition of their environmental consequences (see Muller et al., 2011). This requirement is symmetrical. Environmental policy analysis cannot ignore the market and regulatory context for the products produced along

with the environmental externalities. Two sets of insights have been especially important to reaching this conclusion. The earliest, associated with Buchanan (1969), argued that a monopolistic product market may, by restricting output, serve environmental goals. In this context, imposing effluent charges or restricting emissions with tradable quotas could actually lead to welfare losses.

The logic underlying his result is more general. Judgments about the preferred incentives to realize an efficient resource allocation in an economy with externalities and multiple distortions are potentially complex. One initial stimulus to consider policy design in the presence of existing distortions was the promise of a 'double dividend' from taxes on CO_2 emissions. The logic would rely on using revenues from environmental taxes to reduce marginal tax rates of large, preexisting taxes with significant welfare distortions while maintaining tax revenue. Subsequent research (see Goulder et al., 1999; Bovenberg and Goulder, 2002; Parry et al., 2012) has established that, ignoring environmental benefits, welfare gains are possible with some revenue-neutral switching of environmental taxes for other factor related taxes. In a dynamic model, switches with capital taxes are more likely to lead to welfare gains than switches with labor taxes. Evaluating these revenue-neutral strategies to the use of environmental taxes within deficit reduction policy, Carbone et al. (2012) compare policies using increases in capital, labor, or consumption taxes alone vs using a carbon tax with one of these. Substituting a carbon tax for a capital tax is most efficient (i.e., smallest welfare losses) and for consumption tax the least. Barrage (2012) adds to these findings with a stochastic dynamic general equilibrium model focusing on optimal carbon taxes with preexisting distortions and finds that carbon taxes must be higher if they are undertaken with suboptional preexisting distortion taxes.

Amounts: The Role of Nonmarket Valuation and Benefit–Cost Analysis

Nearly all analyses of policy instruments assume that we have the information needed to decide how much environmental quality to provide. Answering this question involves more than deciding the amount of pollution permitted. It requires that we consider a wide range of natural assets whose amenity services are important to people. Everything from endangered species and their habitat to land and water resources that provide a wide range of outdoor recreation must be considered. Some choices must be made more carefully than others because some allocations of a natural environment will irreversibly alter its ability to provide amenity services (Krutilla, 1967; Krutilla and Fisher, 1975; Pindyck, 2007).

The extent of 'publicness' of the OECs compounds the difficulties in making these choices. Free-riding incentives arising from nonexclusion assure that private action alone cannot be relied upon to realize the efficient level of these types of resources (Cornes and Sandler, 1996; Phaneuf and Requite, forthcoming). Recovering information equivalent to what is provided when market exchanges correctly signal scarcity requires economic 'detective work'. Two strategies have been developed since Hicks (1943) first defined rigorously the monetary representations for the trade-offs defined by economic choices (Freeman, 2003). The first relies on the logic of revealed preference and uses choices of private goods to recover the trade-off information. For example, it recognizes that a consumer's decision to purchase (or rent) a home in an area free of air pollution reflects, in part, a payment for that ambient quality in comparison to the next best alternative (Palmquist, 2005). With a wide array of alternative conditions, the price gradients arising from different air quality conditions, with other housing attributes held constant, would reveal the incremental willingness to pay for improving air quality (Freeman, 2003). Similar logic implies that one could use the trips taken to recreation sites at locations with different travel costs to reveal the demand for the recreation these sites provide (Freeman, 2003). Given a set of recreation sites, varying in quality conditions, consumers' visitation decisions offer the potential to measure the incremental value of those quality dimensions. Decisions to avert or mitigate the negative consequences of pollution offer the same potential to reveal underlying trade-offs (Freeman, 2003).

The logic underlying each strategy relies on reconstructing the unobserved elements required to define the economic trade-off revealed with each choice. In the case of nonmarketed goods this process implies that a connection is also defined between the decision and the OEC of interest. For the trade-off to be informative about an individual's preferences for the nonmarketed good these connections must convey a degree of exclusivity (i.e., economic value of the amenity requires consumption of the linked private good). They must also specify how enhancements in an individual's ability to pay would change them. One way this control over the substitution and income effects of choice is implemented comes from the joint imposition of restrictions on the properties assumed in describing an individual's utility function. Weak complementarity (Mäler, 1974) and the Willig (1978) condition are among the most commonly used. Weak complementarity maintains that the environmental amenity is of value when it is used with the private good. Without some positive consumption of that good, an improvement in the amenity has no value to each person. The Willig condition adds to this restriction a requirement that the incremental value of increases in the amenity, per unit of the private good consumed, does not change with income. This condition together with weak complementarity is sufficient to allow willingness to pay for discrete changes in amenities linked to the private good. Bullock and Minot (2006) have demonstrated that numerical methods can, in some circumstances, allow it to be relaxed.

Stated preference approaches to recovering economic trade-offs offer the second nonmarket valuation strategy. They rely on presenting people believable (but hypothetical) choices with proposed financial consequences and interpreting their stated decisions as bounding economic trade-offs (Mitchell and Carson, 1989; Hanemann, 1994). An important motivation for proposing choices arises from the inability to link all the ways amenities enhance people's well-being to observable choices of private goods. Such unlinked reasons are sometimes referred to as nonuse or existence values (Krutilla, 1967). Stated preference methods are controversial

because they require that survey responses are to be treated as economically consequential (Carson, 2012; Kling et al., 2012; Hausman, 2012).

The primary use for nonmarket valuation estimates has been in benefit–cost analyses (BCAs) of projects involving environmental resources and regulations intended to improve environmental quality. BCAs assume that there are reasons why an existing resource allocation is not efficient. The analysis seeks to evaluate whether an aggregate choice improves the efficiency (Arrow et al., 1996). Four aspects of applying BCA are especially important. First, the net benefits from an aggregate choice are summarized as a present value and are influenced by the time horizon and discount rate used. Both are potentially influential and controversial judgments (see Portney and Weyant, 1999 Sterner and Persson, 2008; Pindyck, 2007). Second, large changes in relation to the overall economy have general equilibrium effects that may require evaluating the effect at the household level and aggregating (i.e., computing net benefits at the household level rather than aggregating benefits and costs separately, see Hazilla and Kopp, 1990; Carbone and Smith, 2013). Third, BCA will always face incomplete information about the changes being evaluated from a baseline to a new outcome. When an irreversible choice is being made and there is the possibility for resolving some of the uncertainty over time, the analysis should include the conditional value of any new information that would be consequential to the decision (Arrow and Fisher, 1974). Finally, monetization of all factors creating benefits or costs is not essential for BCA to be informative. Observed choices (at the individual level) define bounds for the trade-offs implied by a decision. This same logic can be used to delineate bounds for the missing elements in a BCA. That is, we define what the missing elements in a measured value for net benefits would need to be to support a specific choice (Krutilla and Fisher, 1975).

Research Design, Quasi-Experiments, and Measurement

An important lesson that economics brings to the evaluation of policy is that people's behavior matters. The newest literature on policy evaluation in environmental economics has emphasized the importance of research design (see Chay and Greenstone, 2003, 2005; Greenstone and Gallagher, 2008; Davis, 2004; Schlenker and Walker, 2011). Does the empirical strategy used to estimate the effects of pollution on some outcome, whether a health effect or a property value, distinguish this influence from others that may be related? This relationship can arise because other factors are spatially linked or because there are unobservable features of the unit defining each observation that could also affect the specific outcome of interest. This identification problem has been shown to be especially important for environmental applications.

There are two key questions identified in this literature: (1) how can the effects of amenities and disamenities be reliably measured? and (2) when can the estimates from reduced form quasi-experiments, designed to address the first question, be used to evaluate the net gains from new policies? (Kuminoff and Pope, 2014).

Risk: Perceptions and Values

One of the most important classes of OECs involves environmental sources for changes in the probabilities of undesirable outcomes. For example, air pollutants have been associated with premature death and increased episodes of serious illness. These decisions are highlighted for two reasons. First, the framework for evaluating private and public choice must consider attitudes toward risk and the opportunities available to adjust to it. Within a framework that evaluates decisions made before the uncertain events are resolved, there has been considerable discussion of how these risks should affect monetary measures of policy outcomes and discounting. There seems to be broad consensus that attitudes toward risk and opportunities for private and public adjustment should be built into the monetary measures of *ex ante* net benefits and not to the discount rates (Pindyck, 2007). Second, studies of laypersons' risk perceptions and behavior in both experimental and survey contexts suggest discrepancies between subjective beliefs and experts' recommendations. These differences are especially important for small probability and long latency outcomes (Slovic, 1987). Such findings raise questions with what constitutes an informed choice. It has also motivated a growing literature in behavioral economics applied to environmental problems. Much of this literature focuses on the effects of manipulations in the presentation of information or the presentation of default choices to induce specific 'preferred' outcomes (Thaler and Sunstein, 2008). Bernheim and Rangel (2007) have proposed an alternative structure for describing individual choice that seeks to explain seemingly irrational choices as well as the success of these manipulations. Their extension proposes that conventional descriptions of the individual choice process overlook elements of the context for choices and features of the choice alternatives that are important to consumers. In their framework, analysis should focus on understanding these *ancillary conditions*. These types of insights would offer a consistent basis for modifying revealed preference analysis and applied welfare theory. While it has not been used in environmental economics, it offers a promising framework for dealing with discrepancies between objective and subjective beliefs.

Distribution

The term distribution in most economic analyses of policies would lead to a discussion of equity effects, interpreted as evaluating the consequences of actions for different income groups. For environmental policy, distributional considerations are inherently more complex. At least four perspectives have been considered. First, the use of an aggregate net benefits criterion for evaluating policy itself is a distributional judgment. It implies departures from a strict efficiency standard and a willingness to admit policies where there exists the potential for improvements. Positive aggregate net benefits means those gaining could compensate those losing. It does not require the compensation to take place.

The second distributional perspective follows from the identification of long-lived, potentially irreversible externalities – with greenhouse gases and nuclear waste being two widely recognized examples. In these cases, the distribution of costs and benefits extends across generations and the equity issues are often framed in ethical terms. One important implication of this line of reasoning is that policies should treat all generations alike. As a result, this line of reasoning would seem to imply a zero discount rate should be used. However, there is an equally strong intuition from a different perspective suggesting it is not morally acceptable. It implies a decision criterion (i.e., the zero discount rate) that would demand excessively high savings rates of any one generation. This countervailing influence is important because Koopmans' (1960) classic analysis of choice rules over infinite dimensional consumption streams concluded that these rules must display impatience or some amount of positive discounting. Otherwise, it would require the first generation to sacrifice everything. With preference separability over time, Arrow concluded that irreversibility does not change conclusions in favor of intertemporal discounting (see Portney and Weyant, 1999). Of course to the extent preferences or production displays important substitutions or complementarities with irreplaceable environmental resources, then the guidance will depend on the details of those linkages (see Sterner and Persson, 2008).

Economic and environmental feedback effects can have significant distributional consequences within short time horizons. Several cases illustrate how this third perspective can arise. Deciding between CAC vs incentive-based policies can seem clear-cut, considering the total costs of meeting a uniform standard (Tietenberg, 2006). However, the environmental transfer system, linking emissions to ambient concentrations, can imply that the cost savings are realized by allowing the cleanest areas to become dirtier while those exceeding the standard become cleaner. As Evans and Woodward (2013) explain, these factors can also undermine the ability to sustain markets for tradable permits. That is, regulations on the ambient concentrations of other pollutants together with the atmospheric interactions of different pollutants undermine the implicit assumption of independence of the effects of emissions of one type of pollutant from the ambient concentrations of others that are chemically related.

Much less is known about the economic feedback loops connecting environmental policy in one sector to its impacts on others. The economic models used to compute general equilibrium responses usually describe activities as if they all took place at the same 'point in space' (Hazilla and Kopp, 1990). Recent adaptations to these models (Carbone and Smith, 2013) and to household equilibrium location models (Kuminoff et al., 2013) confirm the importance of relaxing these assumptions. Indeed, the results from the equilibrium location model suggest that spatially differentiated, but consistent, air quality improvements can induce housing price adjustments (within a closed system), which imply some households would actually be worse off after an improvement in their air quality. This result arises because the housing price increases induced by some households' relocations can offset the air quality gains for those households with a small taste for environmental public goods.

The last distributional perspective, paradoxically, receives the greatest attention in agencies' design of policies (in the US some legislation specifically identifies concern for the impacts of regulations on small businesses) and often the least in academic discussions. It concerns the impact of regulations on industries and different-sized firms within a sector. Empirical evidence confirms that environmental regulations can have effects on the timing, location, and scale of plant investments. Considering only air quality regulations in the US, they find that activity shifts to areas that meet ambient standards, not subject to stringent area-wide regulations. Less activity takes place in areas that are not in attainment with national ambient air quality standards (see Greenstone, 2002). Greenstone et al. (2012) found using over a million plant-level observations drawn from 1972 to 1993 Annual Survey of Manufacturing Activities that among surviving plants, stricter air quality regulations are associated with approximately a 2.6% decline in total factor productivity.

Growth and the Environment

One of the most durable questions posed in considering interactions between the economy and the environment concerns whether the environmental system poses some 'ultimate limit' on the scale of economic activity (see Barnett and Morse, 1963). Sometimes expressed in terms of raw materials (or natural resources) and other times in terms of ability to provide a sustainable food supply and waste absorptive services to a growing world population, the issue most recently has been expressed in terms of whether growth in income has a self-regulating property. That is, as household income grows, the taste for environmental amenities increases. Providing these services requires reducing pollution, protecting natural environments that provide habitat for endangered species, and enhancing absorptive capacity of ecosystems for some types of pollution.

At one scale, this issue has been posed using what is termed an 'environmental Kuznets curve' (Grossman and Krueger, 1995). Pollution is hypothesized to have an inverted U-shape with household income. It increases until income growth creates demand for amenities that ultimately reduces pollution and leads to policies that restore environmental quality. To date, the questions raised in this line of research have been based on empirical analyses, relying on the contemporaneous performance of economies varying in pollution and household income, as if they could be treated as descriptions of a single economy moving through a dynamic process (Carson, 2010).

This new formulation of the old question is potentially important. It casts the issue in its most relevant form. Economists are concerned about the services provided by environmental resources because market institutions cannot be assured to signal the scarcity of these resources. Understanding both the static distortions to patterns of use and the dynamic nonmarket incentives to bring about changes in the

utilization of these natural assets is important for designing new institutions, which recognize the role of environmental resources in assuring that it is possible to continue to enhance economic well-being.

Abstract

This article attempts a broad characterization of environmental education (EE) and education for sustainable development (ESD), and includes a short overview of the history of the field, key debates, the main approaches to ESD and EE, and a look toward the future. However, such a brief account should not be considered to be fully comprehensive, and can only be considered to provide a broad overview of the field from the authors' perspectives.

Introduction

The ecological crisis and its associated problems in the social, cultural, political, and economic spheres is, in part, the product of ignorance, and as such knowledge of our global dilemma is a prerequisite for addressing it. For many, what we need is nothing less than a new enlightenment, an ecologically based one orientated around the needs of people and planet, and a clear eyed recognition that it is 'unsustainability' not 'sustainability' that characterizes our current global reality (Barry, 2012). Thus, what is needed is to investigate the role of education (both formal and informal) and its role in the transition from current unsustainability.

Environmental education (EE) and education for sustainable development (ESD) are not, nor can they ever be, 'just another' subject to be taught, given the challenges and opportunities outside the classroom and lecture theater to which it addresses. Following the contours and character of the ecological crisis that has given rise to it, ESD necessarily must be interdisciplinary, action-orientated, and holistic and combine both cognitive and conative aspects, as well as integrating both ethical and political analyses. This is a tall order! It is no easy task, but ESD did not create the conditions and problems, which has given rise to its development. Thus, given the knowledge context of unsustainable development, it is vital that a role to be found within the formal education system and outside to recover a sense of purpose fit for the times we live in and the multifaceted challenges and opportunities in the transition from 'actually existing unsustainability' (Barry, 2012).

Definitions and Declarations: a Brief History

EE in its current form emerged in the mid to late 1960s as a response to environmental problems caused through processes of modernity such as industrialization, consumerism, and urbanization. Its precursors included traditions of nature study, natural history, and conservation education. In the UK, the Council for Environmental Education first met in 1968 (Sterling, 2004); the *Journal of Environmental Education* was first published in the United States in 1969, and a seminal article, 'The Concept of Environmental Education,' gave one of the earliest definitions of the field (Stapp, 1969). According to Stapp, the aim of EE was to produce a motivated and knowledgeable citizenry concerning the biophysical environment, its problems, and their solution. Another major objective of EE, in addition to fostering an understanding of the environment and environmental problems and motivation to deal with them, was to ensure that individuals acquired a clear understanding that

> man is an inseparable part of a system, consisting of man, culture [organizational strategies, social processes and social arrangements] and the biophysical environment and that man has the ability to alter the relationships of this system.
>
> Stapp, 1969: 34

The sexist language used in these early declarations has been commented upon by Gough (2013b: 16), who also notes the 'man-made' nature of the foundational discourses of EE – women were largely absent in their formulation, and the discourse is that of a modernist science that separates 'man' and 'nature.' The long association of EE with science education (Gough, 2013a: 10) only began to change in the 1990s with the emergence of more socioecological approaches, which saw the natural science perspective as a simplification and inadequate to address the complex multilayered environmental problems (Kyburz-Gruber, 2013). Gough also argues that this gendered and science-based discourse also had implications in terms of a heavily positivist epistemology and ontology, which influenced much early research in EE (Robottom and Hart, 1993) and also influenced practice. Sterling (2004: 51) notes the early (and still predominant) 'environmental responsibility' view of sustainability education where the major aim was instrumental: changing unsustainable behavior through addressing environmental ignorance. Later studies such as Kollmuss and Agyeman (2002) demonstrated the paucity of such a linear 'deficit' model, and this has been reflected in an increasing emphasis on processes of learning as well as outcomes seen in, for example, socioecological approaches to education involving constructive, reflective, critical, and participatory elements (Kyburz-Gruber, 2013: 24).

The United Nations Conference on the Human Environment in Stockholm (UNEP, 1972), marked one of the first international acknowledgments of human–environmental problems, recommended the establishment of an international program of EE. Following this, a series of international

declarations and initiatives provided a more solid foundation for the emerging 'interdiscipline.' It is interesting that the first of these, in Belgrade Charter (1975), very clearly situated EE within a framework, which acknowledged growing global inequality and the need for a holistic approach to address environmental problems in the context of other issues such as hunger, poverty, illiteracy, and class, racial, and gender exploitation and domination. Possibly reflecting the influence of the *Limits to Growth* study (Meadows et al., 1972), the Belgrade declaration also challenged an uncritical approach to orthodox economic growth and articulated a need for a new global ethic, which not only considered humanity's place within the biosphere, but also would enable change leading to "an equitable distribution of the earth's resources" (Belgrade, 1975: 1–2). The environmental goal for nations was to improve all ecological relationships through clarifying what was meant by such concepts as 'quality of life' and 'human happiness' (Belgrade, 1975: 3). Consequently, the goal of EE was "to develop a world population with the knowledge, skills, attitudes, motivations and commitment to work individually and collectively towards solution to current problems and the prevention of any new ones" (Belgrade, 1975: 3).

The objectives and guiding principles defined in Belgrade were further refined at the first major international intergovernmental conference on environmental education, held in Tbilisi, Georgia in 1977. The subsequent declaration (though not without criticism) was one of the most influential founding documents in the field and laid out the fundamental role, objectives, and characteristics of EE. Those characteristics included its necessarily multidisciplinary nature due to the biological, ethical, social, cultural, and economic aspects of environmental issues. Concepts such as complexity and interdependence were also introduced as key elements. The scope of EE was to encompass lifelong learning, critical and independent thinking within formal and informal learning contexts (UNESCO, 1977). These ideas were to heavily influence subsequent UN initiatives (see Tbilisi, 2012 for a detailed account of these).

Following the Brundtland report (WCED, 1988), which introduced the (much contested) concept of 'sustainable development,' the 1992 United Nations Conference on Environment and Development in Rio (UNEP, 2010) catalyzed a shift in emphasis toward ESD. Agenda 21 Chapter 36 laid out a set of recommendations and actions in education for national governments underpinned by the Tbilisi principles and proposals. Significantly, Agenda 21 stressed the *criticality* of education in "promoting sustainable development and improving the capacity of the people to address environment and development issues" (UNCED, 1992: Chapter 36, para 3). This also brought EE closer to the field of development education, which had emerged via a separate trajectory, involving NGOs and aid agencies and emphasizing individual and collective empowerment, participation, democratization, and social action (Sterling, 2004: 45). Development education brought a more radical set of influences such as the critical pedagogy of Freire (1972). More interpretative approaches to EE research became evident from the 1980s onward, increasing significantly in the 1990s (Gough, 2013b: 18). This coincided with a growth in more constructivist approaches to education generally. The influence of critical pedagogy has also become more prominent. For example, approaches using action research (Reason and Bradbury, 2006) and participatory action research (Tandon, 2008) have increased exponentially since the 1990s (Gough, 2013b: 19).

Further conferences included ECO-ED in Toronto (1992) and Thessaloniki (1997), where the concept of 'Education for a Sustainable Future' was introduced (UNESCO, 1997; Tbilisi, 2012). In Thessaloniki, a broad conceptualization of sustainability that encompassed poverty reduction, health, food, security, democracy, human rights, and peace was emphasized: "Sustainability is, in the final analysis, a moral and ethical imperative in which cultural diversity and traditional knowledge need to be respected" (UNESCO, 1997: para 10). These international initiatives added impetus to existing national strategies and catalyzed action in particular educational sectors. For example, Chhokar (2010) notes that, in 1992, the Indian Supreme Court ruled that EE should be a mandatory part of all higher education. The Talloires declaration (October 1990) included a commitment by university leaders to create cultures of sustainability within their institutions, ensure environmental literacy, and educate for environmentally responsible citizenship; to collaborate internally to promote interdisciplinarity and externally with relevant bodies to contribute to the global effort for sustainability. An organization, University Leaders for a Sustainable Future, was set up and a journal – the *International Journal for Sustainability in Higher Education* was established. The Copernicus Charter played a similar role in Europe.

The next significant development was the establishment of a UN Decade of Education for Sustainable Development (DESD) from 2005 to 2015, following a recommendation made at the World Summit on Sustainable Development in Johannesburg in September 2002 (Tbilisi, 2012). Each member country was encouraged to incorporate ESD into all relevant subjects in their formal education systems and to develop policies and practices to achieve this. Detailed recommendations and a framework for national implementation were outlined in the strategy document (UNECE, 2005). A network of Regional Centres of Expertise was also established to promote learning for a sustainable future (Mochizuki and Fadeeva, 2008). Other supporting initiatives included the Mainstreaming Environment and Sustainability in African Universities (MESA) programme, developed to support the mainstreaming of environment and sustainability concerns into teaching, research, community engagement, and management of universities in Africa.

Sterling (2004: 46) acknowledges that in the first 30 years from the 1960s, a huge amount of work has been done on the underlying philosophy, research methodologies, pedagogy, curricula, resources, communication, and dissemination strategies of EE/ESD, supported and resourced by international bodies such as UNESCO and other NGOs such as the WWF. The agenda has influenced national policies in many countries and many educational sectors, and there has been growing academic involvement and research networks (see also Wals and Blewitt, 2010). However, despite such sustained international attention and commitment, the 2007 Ahmedabad conference on Environmental Education explicitly acknowledged that, "the state of the planet has gone from bad to worse" (Ahmedabad, 2007: 3–4). Regarding EE/ESD (following

another series of international conferences and declarations Gothenburg, 2008; Bonn, 2009; Rio+20, 2012; Tbilisi, 2012), a recent review of the DESD (UNESCO, 2012) evidences mixed progress. ESD is increasingly seen as a means to renew education, teaching, and learning; however, despite a number of inspiring examples around the world, the reality is that, "ESD remains marginal if considered as a separate and distinct entity and commonly understood concept in schools' everyday conversations" (UNESCO, 2012: 85).

More than 40 years since the inception of the field, in the introduction to the *Handbook on Research in Environmental Education*, Stevenson et al. (2013: 2) provide a broad *consensus* on the characteristics of EE as currently manifest. For them, it embraces normative questions: it is interdisciplinary, with environmental, sociocultural, and economic dimensions; agency is important in addition to knowledge, understanding, attitudes, and values; it involves engaged, situated learning, which must also take place in the public domain; and has global and local aspects. In addition to this, perhaps above all else, it is explicitly (though unevenly) viewed as a political and transformative project. However, the breadth and, some would argue, necessary vagueness of terms used to define ESD have meant that the EE/ESD project has been widely criticized and to some extent fragmented (Sterling, 2004). The next section hence addresses key conflicts and contradictions in the field.

Problems and Key Contradictions

As discussed above, if we were to assess the effectiveness of the ESD project in terms of lessening what Barry (2012) has termed 'actually existing unsustainability,' we might conclude that there has been limited (if any) progress. One possible reason for this might be lack of implementation of the many declarations on ESD: Filho (2012), in a commentary preceding the Rio+20 summit, observes that the majority of declarations and action plans have never been fully implemented, particularly at regional and local levels. Martin et al. (2013: 1537), commenting generally on the DESD, note that most evidence indicates a rather ill-focused and half-hearted awareness raising campaign leading to a patchy impact and limited engagement. However, problems may run deeper than a failure to implement broadly agreed international strategies. Cook et al. (2010: 313–314) raise the question that "formal education, as it is currently organized is incapable *of* coming to grips with the problem?"

One core contradiction here is that ESD is mostly conducted within political and educational systems whose basic assumptions, particularly those underpinning how their economies are run, might fundamentally militate against ecological sustainability. As Wals and Corcoran (2012) note, it is impossible to examine questions of sustainability education without acknowledging the other processes taking place in society that are moving us toward unsustainability; these raise ethical and political issues of the unequal distribution of power and agency, social injustice, in addition to uncertainty and other complexities. This contradiction has been acknowledged as early as 1974 when the Institute for Earth Education was set up in the United States (Van Matre, 1990) on the basis that EE had been trivialized and diluted by both mainstream education and the agencies and industries who themselves are the main contributors to continuing unsustainability problems. David Selby points out the thorny problem of how a democratic citizenry, "immured in a pervasive consumerist ethic, can be squared with an environmental narrative predicated on the finiteness of the earth" Selby (2011: 10). The way that formal education systems themselves are structured and their fundamental epistemological objectives clearly militate against effective, that is, *transformative forms of ESD*. For example, one evaluation of the progress of the DESD (UNESCO, 2012: 86) suggests that colleges and universities around the world are starting to make more systemic changes toward sustainability, "amid educational reforms toward efficiency, accountability, privatization, and forms of management and control processes that often hamper their efforts" (UNESCO, 2012: 86). That is, the reform process within higher education institutions offers an unconducive context for ESD.

Other criticisms of ESD include the overemphasis of a tendency to view the student as an *individual* actor. As Scott and Gough put, this "neglects the picture of the student as a social and more public actor – as someone engaged in the messy but vital business of democratic citizenship that is so central to the received view of sustainable development and ESD" (Scott and Gough, 2010: 3737). This [individualized] view also lends itself to a serious dilution of a necessary politicized approach to learning and acting about current unsustainability and the transition to resilience and sustainability. However, the danger that such a politicized approach might turn prescriptive or dogmatic in certain cases has also been articulated: Sund and Lysgaard (2013) note that prescriptive, normative forms of ESD, which focus on learning outcomes as opposed to learning processes are problematic, as they often neglect educational best practice. Earlier criticisms of ESD concern politically prescriptive, dogmatic content using "emotionalism, myths and misinformation" (Kwong, 1997: 90). This raises the dilemma of how normative and ethical issues can be *effectively* explored in educational settings in a nondogmatic way, given the urgency of the need for change. The next section thus addresses a range of approaches to EE/ESD.

Approaches to EE/ESD: Moving Toward a Paradigm Shift

In 1993, three basic paradigms were identified by Robottom and Hart, roughly corresponding to the dominant research paradigms of the time: positivist, interpretivist, and critical. To these, Fien (2002) has added poststructuralism and more recently, Gough (2013b: 19) has noted the increasing influence of poststructuralism and multivoice, multicentred studies foregrounding indigenous knowledge, postcolonial and feminist perspectives, in addition to work on socioecological resilience. These basic paradigms or worldviews reflect particular approaches to education.

Vare and Scott (2007: 191) identify *instrumental* ESD, or ESD 1, as "the promotion of informed, skilled behaviours and ways of thinking," reflecting a more behavioristic, outcome-focused approach. The *intrinsic* ESD approach or ESD 2 is concerned with individual learning and involves "building capacity to think critically about what experts say and to test

ideas, exploring the dilemmas and contradictions inherent in sustainable living" (Vare and Scott, 2007: 191). This is based on a more constructivist educational philosophy and as such focuses more on the processes of learning (e.g., Wals, 2006). A third, more critical, approach to EE is concerned with social learning. Scott and Gough (2010: 3743) argue that "ESD can helpfully be seen as an education in citizenship: a responsive social learning process which is a preparation for informed, open-minded, social engagement with the main existential issues of the day that can be experienced in the family, the community and workplace, indeed, in all aspects of lifelong learning." More radical approaches derive from explicitly political and critical pedagogies (e.g., Freire, 1972), which place an emphasis on education for social and political transformation (see also Huckle, 2008). However, Freire's critical pedagogy, as well as other liberal education approaches such as Dewey's, has been criticized by Bowers (2005) who argues that the one key mistake these approaches have made is to assume that there is one 'true' approach to learning. To counter this, Bowers advocates examining "ecologically problematic cultural assumptions" (Bowers, 2005: 13) to dominant knowledge (including 'commonsense' taken for granted ideas of 'economic growth' as an agreed societal imperative), and a reappraisal of local knowledge systems and traditions reflects cultural and bioregional diversity.

The acknowledgment that content studied processes of learning, and diverse regional and political contexts of learning are *all* important, have led to more integrative models of ESD, utilizing social–ecological systems approaches. This shift can be seen in the work of educators such as Stephen Sterling (2003), who, echoing O'Sullivan (1999) note that (notwithstanding some essential differences) critical, transformative pedagogy and ESD can be complementary. For example, Sterling's (2003) model of 'sustainable education' essentially integrates and transcends a range of existing approaches and adopts a whole systems thinking approach, which he equates with a "postmodern ecological worldview" (Sterling, 2003: 39). Gregory Bateson's (1972) 'levels of learning' are used as a frame to enable the examination of learning in different contexts, and in different ways, all of which may have their uses. Learning 1 or learning within paradigm (a particular set of choices for action available within a particular worldview) can be seen as roughly corresponding to more instrumental forms of ESD or to "single-loop learning" (Argyris and Schön, 1996). Learning 2, more closely associated with critical thinking, and Argyris and Schon's "double-loop learning" involves awareness of alternative paradigms or worldviews that frame sets of choices. The third level of learning identified by Bateson, is essentially transformative, involving a more enlightened self-awareness of what frames choice in the individual. Thus, Sterling conceptualizes 'sustainable education' as:

> a change of educational culture which both develops and embodies the theory and practice of sustainability in a way which is critically aware. This would be a transformative paradigm which values, sustains and realizes human potential in relation to the need to attain and sustain social, economic and ecological well-being, recognizing that they are interdependent.
>
> Sterling, 2003: 233

This broader view incorporates individual, organizational, and social transformation and can also provide a pragmatic basis for change in existing formal education systems. For example, to engender change in higher education institutes, Jones et al. (2010), in common with many ESD practitioners advocate the use of a holistic definition of sustainability that brings into play dimensions of culture, economy, health, peace, and conflict, human rights, gender equality, science and technology, and social, global and intergenerational justice. This broader view also links to other more psychological approaches to how ESD can motivate behavioral change, i.e., move from critical thinking to action, such as the reasoned action approach (Fishbein and Ajzen, 2010). Multifaceted approaches inspire exploration of alternative problem definitions and solutions, and foster deliberation and debate, which require contribution from a wide range of disciplines.

Models such as Sterling's, by integrating and effectively transcending a number of approaches, thus fulfill the requirement articulated by the Ahmedabad conference (2007: 4) for "fundamental change in the purpose and practice of education." The American College and University Presidents' Climate Commitment, following Cortese (2003), describe what such change might look like in higher education:

> - The *context* of learning would change to make human/environment interdependence, values and ethics a seamless and central part of teaching of all the disciplines, campus operations should be sustainable, and partnership should occur between local, regional and global communities.
> - The *content* of learning would further reflect interdisciplinary systems thinking, dynamics and analysis for all majors and disciplines and bring lateral rigor across the disciplines as well as the vertical rigor currently within them.
> - The *process* of education would complement formal curriculum with active, experiential, inquiry-based learning and real-world problem solving both campus-based and within the larger community.
>
> ACUPCC, 2009: 6

Emerging areas in higher education, which reflect such a paradigm shift include the emerging field of sustainability science that: "seeks to understand the fundamental character of interactions between nature and society" (Kates et al., 2001: 641).

Moving toward the Future: ESD and the Building of Resilient Communities

A more recent movement in EE/ESD, reflecting the need to address emerging and potential environmental problems, has been in the area of learning for resilience and in examining the role of learning in the building of resilient communities in the context of exacerbating ecological and resource problems, such as climate change and 'peak oil.' This has been influenced by grassroots movements, such as the 'transition towns' movement (Hopkins, 2008; Barry, 2012), and studies of resilience and adaptive capacity in

socioecological systems (e.g., Folke et al., 2002). This also reflects a shift from more reductionist paradigms toward a complex adaptive systems worldview (Barry, 2012), which can be seen in fields such as education, ecology, ecosystem management, and reflexive governance for sustainability. This worldview sees reality as complex and dynamic, there is no 'one right answer,' and sustainability and resilience are seen as emergent properties of specific social–ecological systems. Thus sustainability and resilience (and therefore education for both) will differ in different socioecological contexts so that ESD/EE in Belfast will not necessarily be the same as EE/ESD in Boston, Berlin, or Beijing.

Thus, building resilience in bioregions involves "diagnosing, mapping and adapting to" (Giddens, 2009: 163) existing and *emerging* vulnerabilities. It also involves attending to "slowly-changing, fundamental variables that create memory, legacy, diversity, and the capacity to innovate in both social and ecological components of the system" (Folke et al., 2002: 8). This implies *on-going* processes of learning, innovation, and knowledge creation utilizing a diverse range of existing and historical knowledge and skills. In this way, learning for resilience occurs at different levels: individual, group, community, organization – and in different settings (home, school, work, street, community, formal and informal contexts, etc.). Sterling (2010) equates the resilient learner with the *intrinsic* approach to sustainability education (Vare and Scott, 2007), focused on building the capacity in the individual to be critically aware, inquire, and learn. How individuals collectively learn is also important in building resilience at community and societal levels. Lundholm and Plummer (2010), citing Glasser (2007), note that social learning depends on the maturity and competence of the individuals involved and the rules that guide particular organizational learning, public participation, and decision-making processes. Thus learning for resilience is lifelong, both responsive and anticipatory, and multifaceted. It requires a rethink of how learning and institutions of learning are structured, to reflect a more outward-looking social focus and provide a public resource for learning, action, and political transformation. And given the continuing unsustainability of human–nature relations, ESD must also be seen as an essential element in creating a "safe operating space for humanity" (Rockström et al., 2009).

Conclusion

At a fundamental level, Thomas Berry cites the relationship between humans and the other than human components that we live in as the "missing element" in education (Berry, in O'Sullivan, 1999: x). For Berry, educationalists have forgotten that "we and all our institutes of learning are primarily in a learning position in reference to the larger world around us," and that "every occupation must be established *within* the integral functioning of the planet" (O'Sullivan, 1999: xiv, emphasis added). Thus, there is an imperative to renew "our acquaintance with the sensuous world in which our techniques and technologies are all rooted" (Abram, 1996: x). To this end, Orr (2004) notes that education should be reshaped in a way that fosters cultivation of 'biophilia' ("the urge to affiliate with other forms of life" Wilson (1984)), a process that should begin in childhood and continue throughout life. Such an approach is evident in earth education (Van Matre, 1990), forest education (www.foresteducation.org), and the civic ecology (www.civicecology.org) movements – effectively outdoor and/or community-based education, which will draw out "our affinity for life" (Orr, 2004: 213), and foster a love of nature. The idea of 'sustainability competence' (Wals and Corcoran, 2012: 24) thus includes the ability to put oneself in the mind of others, even other species, having different backgrounds or living elsewhere, in addition to abilities to see relationships and interdependencies and to envision future implications.

However, to be effective in addressing existing forces of unsustainability, ESD must (in our view) be profoundly *political* and aimed at real world transformation (Barry, 2007). As mentioned above, almost 40 years ago, the Belgrade (1975) very clearly situated EE within an ethical and political framework, which would enable change leading to "an equitable distribution of the earth's resources […] more fairly satisfying the needs of all people" (Belgrade, 1975: 2) and improve socioecological relationships through clarifying what was meant by such concepts as 'quality of life' and 'human happiness' (Belgrade, 1975: 3). To grow such an ethical framework requires broader, systemic, and political conceptualizations of ESD incorporating individual and social learning, in addition to the acquisition of practical skills and diverse knowledge. As the 2007 Ahmedabad conference noted, "we need recommendations that help alter our economic and production systems, and ways of living radically. We need an educational framework that not only follows such radical changes, but can take the lead" (Ahmedabad, 2007: 4). And, in that way, we find that both EE and ESD are, properly speaking, concerned not so much with humanity 'learning' about nature, but learning about ourselves and nature within the central learning objective of how to understand and ultimately transform our species' foundational and ineliminable relationship with the nonhuman world.

Abstract

Environmental health factors play a significant role in human health and the protection of the environment. The health impacts resulting from exposure to these factors are closely linked to social aspects such as socioeconomic status and access to health care. Three current environmental case studies are discussed from both an environmental and a social aspect.

Introduction

As a cornerstone of public health, environmental health factors play a significant role in human morbidity and mortality in both developing and developed countries across the globe. The World Health Organization (WHO) recognizes the impact of these factors and has adopted a two-stranded definition of environmental health that embraces both the etiology of health problems and also the methodologies to manage them.

> Environmental health addresses all the physical, chemical, and biological factors external to a person, and all the related factors impacting behaviors. It encompasses the assessment and control of those environmental factors that can potentially affect health. It is targeted towards preventing disease and creating health-supportive environments.
> (WHO, 2013a)

In a 2006 WHO Report, "Preventing disease through healthy environments: Toward an estimate of the environmental burden of disease," Pruss-Ustun and Corvalan reported that an estimated 24% of the global burden of disease and 23% of all premature mortality can be attributable to environmental factors with the specific fraction of disease attributable to the environment varying widely across different disease conditions due to differences in environmental exposures and access across the regions. In 2013, WHO (2013a) listed 10 facts on preventing death, illness, and disability through healthy environments, highlighting the need for environmental management of potential hazards. These statements highlight the disproportionate impact of environmental factors on vulnerable populations, particularly the impoverished in developing countries.

- 'Worldwide, 13 million deaths could be prevented every year by making our environments healthier.
- In children under the age of five, one-third of all disease is caused by the environmental factors such as unsafe water and air pollution.
- Every year, the lives of four million children under 5 years of age – mostly in developing countries – could be saved by preventing environmental risks such as unsafe water and polluted air.
- In developing countries, the main environmentally caused diseases are diarrheal disease, lower respiratory infections, unintentional injuries, and malaria.
- Better environmental management could prevent 40% of deaths from malaria, 41% of deaths from lower respiratory infections, and 94% of deaths from diarrheal disease – three of the world's biggest childhood killers.
- In the least developed countries, one-third of death and disease is a direct result of environmental causes.
- In developed countries, healthier environments could significantly reduce the incidence of cancers, cardiovascular diseases, asthma, lower respiratory infections, musculoskeletal diseases, road traffic injuries, poisonings, and drownings.
- Environmental factors influence 85 out of the 102 categories of diseases and injuries listed in the 2004 World Health Report (WHO, 2013a).
- Much of this death, illness, and disability could be prevented through well-targeted interventions such as promoting safe household water storage, better hygiene measures, and the use of cleaner and safer fuels.
- Other interventions that can make environments healthier include: increasing the safety of buildings; promoting safe, careful use, and management of toxic substances at home and in the workplace; and better water resource management.'

Environmental determinants of health have traditionally focused on areas of underdevelopment such as inadequate water quality, inadequate sanitation and waste disposal, presence of disease vectors, and poor housing. While most of these areas have been managed successfully in developed countries, they are still major causes of morbidity and mortality in less developed counties (Liamputtong et al., 2012). Paradoxically, many countries are now faced with modern threats that have emerged due to overconsumption and overdevelopment, compounded by emerging threats such as climate change. These new hazards are the result of often uncontrolled development activities occurring without sufficient safeguards and unsustainable consumption of natural resources (Earl et al., 2012; SERI et al., 2009). The Health Council of the Netherlands (2012) also noted that in Western nations, increased health risks are usually related to an accumulation of unfavorable physical and social circumstances. Rapid urbanization and large-scale movements of people have introduced a whole new set of environmental health hazards while exacerbating others (Margai, 2012).

Figure 1 The main determinants of health. Dahlgren, G., Whitehead, M., 1991. Policies and Strategies to Promote Social Equity in Health. Institute for Further Studies, Stockholm.

In addition to environmental factors, human health is affected by many other interrelated and overlapping factors. One widely accepted model, which captures the interrelationships between various factors that affect human health is the Dahlgren and Whitehead (1991) 'Policy Rainbow' (**Figure 1**). This rainbow model conceptualizes the main determinants of population health and demonstrates the connections between health and socioeconomic, environmental, and cultural conditions. The inner layer represents personal factors and behaviors, the middle layer is the social and community networks that ideally support individuals as well as groups and families, and the outer layer is the environmental and social factors that play a more encompassing or overarching role in determining health. This reinforces the concept that despite favorable lifestyle factors and community support, environmental, cultural, and general economic conditions ultimately determine the state of human health.

In 2012, the Health Council of the Netherlands released a report on the "Social Aspects of the Living Environment in Relation to Environmental Health." They also noted that numerous relationships play a role in environmental-related health problems and that exposure to various environmental stressors or hazards can have a broad range of effects, with specific problems often the result of several stressors interacting on human health. The authors also noted that environmental stressors do not always have the same effect on health and that in addition to context and exposure, this is largely dependent on the social determinants of health which are the social, cultural, economic, environmental, and political factors that can impact on the health of individuals.

Social Determinants of Health

The WHO Commission on Social Determinants of Health broadly defines social determinants as "… the circumstances in which we are born; grow up, live, work and age, and the systems put in place to deal with illness. These circumstances are in turn shaped by a wider set of forces such as economics, social policies and politics" (WHO CSDH, 2008: p. 1). These are all factors that impact on our vulnerability or immediate coping capacity as well as our ability to adapt to changing situations. In the WHO publication, *The Solid Facts*, Wilkinson and Marmot (2003) and Marmot and Wilkinson (2006) list and discuss the 10 widely accepted social determinants of health, from social status differences to transportation. All of these determinants have environmental dimensions. For example, social inequality can be linked to overcrowding and substandard housing, which in turn may increase the risk of exposure to contaminated air or unclean water.

Vulnerability and Human Health

The impact of environmental hazards on human health is generally dependent on the vulnerability of the affected population. What becomes apparent when looking at the morbidity distribution of illness and disease caused by environmental factors is that the health impacts of these factors disproportionately affect the poor and isolated, both those in developing countries as well as the socially disadvantaged groups in developed countries. These people are vulnerable in that not only are they unable to respond appropriately to cope with the immediate effects of environmental hazards or incidents, but also they are less likely to be able to recover and adapt their circumstances and situation to minimize ongoing impacts and mitigate or prevent effects from future events.

The social aspects of vulnerability are recognized although it is acknowledged that little is known about them as they are difficult to quantify. Social vulnerability is partially a product of social inequalities and also includes place inequalities, i.e., differences in community such as level of urbanization,

infrastructure, and governance. In 2003, Cutter, Boruff, and Shirley constructed an index of social vulnerability called the Social Vulnerability Index by looking at conditions that contribute to making people or places vulnerable to extreme natural events. They also looked at communities' resistance or resilience to hazards. Using a factor analysis approach and based on US data, they found that there were 11 factors that accounted for over 75% of the variance in vulnerability. Factors identified included personal wealth (of countries), age (elderly and young especially vulnerable), density of the built environment (manufacturing and commercial establishments) housing, single sector economic dependence (especially agricultural as it is very climate dependent), housing stock (quality), tenancy (home ownership, renters, mobile homes, etc), race and ethnicity (marginalization with racial disparities), occupation and finally infrastructure dependence (economic vitality and revenue generating capacity).

Environmental Case Studies

Previous discussion has focused on the magnitude and scope of the possible effects social determinants may have on the outcomes of environmental conditions and incidents. It should be noted that environmental incidents themselves can also have a significant impact on social and psychosocial determinants such as employment, social exclusion, social support, socioeconomic status, and in particular, stress. This section will discuss three very significant twenty-first century examples of environmental phenomenon or *disasters* that have had far reaching social as well as environmental implications: Climate change, the 2010 Deepwater Horizon oil spill, and the 2011 nuclear accident in Fukushima, Japan. Climate change is a unique environmental phenomenon in that it has the potential to affect ecosystems and populations all over the world. The drivers of climate change have been occurring over decades, basically since the industrial revolution, with changes to our surroundings so subtle that they have gone relatively unheeded for many years. The other two examples involve technological failures that have caused immediate devastation over a more defined area and both continue to be the subject of long-term ongoing attempts at cleanup and restoration.

Health Impacts of Climate Change

Climate change is an emerging threat to public health that has the potential to have extremely significant health and social impacts, as both a direct and indirect consequence of the effects on the environment. The environmental manifestations range from mild fluctuations in weather patterns to the catastrophic destruction that may result from an increase in both the frequency and intensity of extreme weather events such as storms, cyclones, flooding, and heat and cold waves. While there may be some positive effects of climate change, such as lower cold-related mortality, changes in agricultural yields, or vector survival rates in some areas (Confalonieri et al., 2007), the majority of impacts are predicted to be negative. There are also predicted to be significant social effects from the potential displacement of large numbers of people both from coastal areas in low lying countries and agricultural areas that are no longer viable or able to sustain crops and livestock. This displacement may lead to the loss of social infrastructure and support, unemployment and poverty, as well as psychological distress.

Climate change has the potential to cause a broad range of impacts by various direct and indirect pathways (**Figure 2**). Human health may be affected directly through phenomena such as heat and cold waves, drought and extreme weather events such as storms, tsunamis, and cyclones. Indirect effects that may be detrimental to health generally result from changes to existing conditions such as an increase in the formation, dispersion, and deposition of air pollutants such as ozone and particulates and changes in water quality and availability. There may also be corresponding changes in vector ecology and ecosystems, with subsequent changes in communicable disease as well as changes to agriculture and food quality, industry, and settlements. Climate change can also cause social and economic disruption by forcing the displacement of populations following adverse weather conditions such as droughts and floods, extreme weather events, and also the loss of coastal regions due to rising water levels. There may also be a financial burden associated with property and personal loss as well as a reduction in personal wealth associated with displacement (Kreigler et al., 2012; WHO, 2013b).

As illustrated in **Figure 2**, environmental, social, and health system conditions all have the potential to have a modifying influence on the health impacts of climate change as they are all fundamental to determining adaptive capacity. From an environmental aspect, the prevailing environmental conditions will have a large bearing on the outcomes of any change. The higher the standard of water and air quality, the lesser the effect is likely to be. In countries that already have poor water, air, and soil quality, a further reduction in quality may have a devastating effect. The geography of a community will also be important with low lying or drought-prone areas being particularly vulnerable. Social conditions such as community organization, employment, and economic status will all be important in determining the resilience and adaptability of a community or county to the possible effects of climate change. Health system conditions such as access, affordability, and quality of health care will also be important determinants of health impacts (Confalonieri et al., 2007).

As a relatively recently recognized and studied phenomenon, there is little long-term epidemiological evidence about the effects of climate change. Research into climate change impacts and adaptation is particularly complex due to the many uncertainties surrounding the various ecosystems' responses to warming, as well as the difficulty associated with contextualizing the heterogeneity in impacts and adaptive capacity (Kreigler et al., 2012). In many parts of the world there has been very limited funding available especially where there has been a history of skepticism regarding the scope and magnitude of the predicted outcomes. Despite the limited research that has occurred, it is generally acknowledged that the key to mitigating the potential effects lies in a country or a population's adaptive capacity. Many developed countries appear to have refocused their priorities and rather than trying to reduce greenhouse emissions and slow the potential effects, they are instead investing in researching adaptation strategies to reduce the adverse consequences for various future scenarios.

Figure 2 Schematic diagram of pathways by which climate change affects health, and concurrent direct-acting and modifying (conditioning) influences of environmental, social, and health system factors. Confalonieri, U., Menne, B., Akhtar, R., Ebi, K., Hauengue, M., Kovats, R., Revich, B., Woodward, A., 2007: Human health. Climate change 2007: impacts, adaptation and vulnerability. In: Parry, M., Canziani, O., Palutikof, J., van der Linden, P., Hanson, C. (Eds.), Contribution of Working Group II to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change. Cambridge University Press, Cambridge.

Given that these strategies require significant financial investment, it follows that developing nations who have extremely limited finances and therefore a limited capacity to adapt will be impacted far more severely. Many of these countries already have high rates of disease and debility and are less able to cope successfully with stresses of all kinds, including the environmental and social impacts of climate change (NCCARF, 2013; WHO, 2013b).

Deepwater Horizon Oil Spill

In April 2010, a system malfunction on the Deepwater Horizon mobile offshore drilling rig, situated in the Gulf of Mexico, led to an explosion that killed 11 workers, injured 17 others, and caused large quantities of crude oil to be released. By the time the well was capped 87 days later, the equivalent of 4.9 million barrels of crude oil had escaped into the Gulf, making it the largest oil spill in recorded history (Ramseur and Hagerty, 2013). The oil slick covered 6500 km^2 of ocean and polluted hundreds of kilometers of beaches, wetlands, and estuaries on the Gulf leading to a complete loss of vegetation in some areas and the death of thousands of fish, birds, and mammals. The cleanup was also surrounded in controversy over the use and quantity (at least 6.8 million liters) of dispersants which contained both carcinogens and endocrine disrupting chemicals, and are now known to have increased the toxicity of the oil up to 50 times through a synergistic effect. There were also serious environmental concerns about in situ burning of the oil, which released dioxins and other harmful chemicals into the atmosphere (Rico-Martinez et al., 2013).

Following the oil spill, fishing areas were closed and fears about sea food safety lead to a dramatic reduction in local sea food harvesting even in areas away from where the oil spill reached resulting in people working in the commercial fishing industry losing their employment and sea food prices rising in the USA (Grattan et al., 2011). There was also a decrease in tourism in the coastal areas affected by the oil spill with a loss of over 400 000 tourism jobs (Diaz, 2013). Lack of fishing and tourism caused substantial economic hardship to the residents in the area (Cleveland, 2013).

Oil spills contain a mixture of chemicals that can include benzene, polycyclic aromatic hydrocarbons, toluene, xylenes, ethylbenzene, and other compounds that may be toxic to human health (Mendelssohn et al., 2012). An article by Levy and Nassetta (2011) analyzing previous studies on the health effects of oil spills identified that in addition to acute and chronic physical health effects, oil spill cleanup workers also suffered psychological disorders. In 2010, a study of 1200 residents who lived within 16 km of the affected coastline reported that one-third of parents indicated that their children experienced mental health distress or physical ill-health (mainly respiratory symptoms and skin irritations) as a direct result of the oil spill (Abramson et al., 2010). Twenty-five percent of the coastal residents interviewed were planning to move from their home and the coastal area due to the effects of the oil spill. Children's leisure activities were also changed with 84% of parents decreasing their children's swimming time, 81.8% decreasing fishing time, 73.2% decreasing boating time, and 65% of parents believing that local sea food was not safe to eat. Woodward (2010: p. 1292) reported that Gulf States residents who lived close to the areas of the oil spill, and people whose business had decreased or closed due to the oil spills "have been exhibiting signs of acute anxiety, depression, increased and excessive drinking, and

suicidal ideation" which may contribute to mental health issues in children.

Research conducted by Lee and Blanchard (2012) found that after the Deepwater Horizon disaster, community attachment, and the fear of losing members of the community, was a problem, particularly for residents who had lived in an area for generations working in the fishing industry or in the oil industry, or who were of Cajun descent, who were unwilling to relocate when there was no longer work available in their community. These residents were highly susceptible to psychological trauma when economic loss occurred. Community indignation about the Deepwater Horizon oil spill amplified resident's fear, anxiety, and worry (Lee and Blanchard, 2012). Grattan et al. (2011) conducted research comparing the psychological impacts of the Deepwater Horizon oil spill on people who had direct experience dealing with the spill with those that suffered economic loss due to the oil spill, but who were located away from the coast where the oil spill reached. They found that participants with oil spill related income loss had higher scores for being depressed, having tension, anxiety, fatigue, confusion, mood disturbances, and had lower scores for being resilient. They were more likely to use behavioral disengagement (withdrawal from society) as a coping strategy. Levy and Nassetta (2011) reported post-disaster changes in the community including struggling over where to place blame. Poor risk communication following the event with authorities being evasive and unresponsive led to the community, particularly affected individuals becoming suspicious and cynical.

Fukushima Nuclear Power Plant Accident

In March 2011 an earthquake of magnitude 9 in the Pacific Ocean (Tōhoku) triggered a tsunami that inundated the north east coast of mainland Japan. This caused the loss of cooling to four reactors at the Fukushima Daiichi nuclear power plant, which led to a partial meltdown and exposure of spent fuel stores and the consequent release of significant amounts of radiation into the surrounding environment (Murayama, 2012; Prati and Zani, 2012). The incident rated 7 on the International Atomic Energy Agency rating scale, which is the highest possible level and equal to the level given to the catastrophic meltdown that occurred at Chernobyl in 1986, even though the total amount of radiation released was considerably less. In a 2011, discussion paper questioning the ethical issues surrounding nuclear energy, Blowers (2011: p. 73) described the event as "a cataclysmic event, creating widespread ecological devastation, displacement of population, economic catastrophe, social disruption and psychological trauma." The author also noted that the effects are likely to persist far into the future. An independent investigation by a National Diet of Japan (2012) Commission into the accident reported that while the cause of the accident was clearly attributable to natural phenomena, the resulting nuclear accident was "a profoundly manmade disaster – that could have and should have been foreseen and prevented" (p. 9).

Although no short-term radiation exposure fatalities were reported, there were approximately 18 500 deaths directly related to the earthquake and tsunami. Estimates of the health and social impacts from exposure to radiation are only speculative, however, as based on the experiences with Chernobyl, there is likely to be a long-term, possibly permanent disruption and dislocation for people who lived and worked in what is now an exclusion zone. They have been forced to abandon their homes, communities, livestock, and livelihoods at short notice and are no longer able to live in their own homes or neighborhoods (Blowers, 2011).

The differing views on the health effects of low radiation doses made communication about radiological health risks particularly difficult. After the accident the level of risk communicated to the public differed significantly between local and national governments. Several standards for radioactive substances in food and drinking water and for radiation levels in school facilities were relaxed leading to distrust in the judgment of the national government (Murayama, 2012). The survivors felt powerless and lacking control over their future, especially when faced with unknown future health effects for themselves and future generations (Blowers, 2011). In the 5 months following the incident approximately 27 000 people moved out of the Fukushima Prefecture. The continued decrease in population in the area made it clear that anxiety about radiation risk had a significant social effect leading to the collapse of local communities in the Prefecture. Localized citizen activist groups also emerged and anxiety about radiation risks also appeared to have an adverse effect on the price of agricultural produce in the area.

Nuclear energy presents an ethical dilemma in that worldwide concerns about the effects of carbon dioxide levels on climate change have in fact driven the push for the development of alternative noncarbon dioxide emitting energy sources. The incident at Fukushima occurred at a time when people were beginning to accept nuclear power as safe, *clean*, and reliable. Twenty-five years on from Chernobyl, it appeared that it was now an economically viable alternative and proponents promote it as an extremely efficient, low-carbon emitting option to highly polluting fossil fuels. Environmental concerns have been pushed aside by fears of climate change, energy security, and concern about dependence on foreign energy supplies (Blowers, 2011). While it is unlikely that the Fukushima incident will ever be replicated, the demand for cheap, efficient, and reliable power puts increasing pressure on new high-risk technologies that are being developed on a larger and faster scale than ever before.

In addition to influencing the feelings of those most directly affected by the disaster, the Fukushima accident has also changed public perception in other countries not affected. In 2012, Prati and Zani hypothesized that a major nuclear accident may affect the most durable cognitive and cultural foundations that underpin public perceptions of nuclear power. Their studies included only Italian participants and reported decreases in nuclear trust, environmental organization trust and pronuclear attitudes as well as changes in risk perception, and antinuclear behavioral intentions. Despite a relatively small sample size, they concluded that major accidents may have the potential to influence values and proenvironmental beliefs. Their research provides support for the notion that a nuclear accident may have a deep impact on public views regarding nuclear power in the short term.

Sustainability and Future Challenges

The environment is a major determinant of human health and well-being. Despite advances in knowledge regarding the links between human health and the environment, there continues to be unprecedented exploitation of the natural environment to meet the needs and desires of the current population. Natural resources such as water, air, and fertile land which are fundamental to our existence continue to be exploited, with humans today extracting and using approximately 50% more of our natural resources than we did 30 years ago (SERI, 2009). There is growing concern that if scarce resources are depleted at an unsustainable rate they will not be available to future generations. A 2009 Sustainable European Research Institute report on the global use of resources noted the inequitable consumption of resources across the planet. People in rich countries were found to consume up to 10 times more natural resources than those in the poorest countries, even though many of the resources have actually been extracted from the poorer countries. In many cases the rush for more secure, reliable, and financially viable energy sources has often meant that the precautionary principle, as it applies to development, has been set aside, leading to potential exposure to both traditional and new hazards from technological advances such as nuclear energy and fracking.

Earlier this century Al Gore, a former US presidential candidate, took environmental issues to the world arena and in doing so raised awareness of the links between our actions, the health of the environment, and impacts on human health. At a grassroots level this increased awareness has empowered groups and communities and given rise to an increasing number of environmental or *green* groups whose agenda is fundamentally the protection of the environment and ultimately human health. Concern for the environment and human health is now firmly entrenched on the political agenda, with the governments of many countries now containing members from parties whose platform is based on socially responsible and humanitarian sustainable development.

Environmental and social determinants both play a very significant role in the health and well-being of all inhabitants of the earth, whether they live in affluent communities in developed countries, the slums of poorer developing countries, or belong to a vulnerable group. The challenge for the future is to recognize the strong connections between these determinants if sustained improvement in global community health and well-being, as well as protection of the environment, is to be achieved.

Abstract

This article looks at the environmental history of the empire by looking at histories of environmental change in the tropics by pioneering colonial scientists and by contemporary historians who are carving out the domain of colonial environmental history. The article argues that the development of an environmental sensibility can be traced to the encounter of seventeenth and eighteenth century Western Europeans especially naturalists, medical officers and administrators with the startlingly unfamiliar environments of the tropics and with the damage done to these environments by them.

Introduction

What is environmental history and why should we do it? Environmental History has been described variously as the interdisciplinary study of the relations of culture, technology and nature through time by historians such as Donald Worster and as the historically documented part of the story of the life and death, not of human individuals but of societies and species, in terms of their relationship with the world around them by Richard Grove and Mark Elvin. Clearly some environmental historians argue from a materialist/structuralist perspective while others argue from much more of a cultural perspective. There is some disagreement about whether the natural world constitutes any kind of order or pattern that we can know and, if it does, whether that order can be apprehended by means of science or not. There is also debate on what is natural and what is not, whether indigenous people managed the whole environment or only some part of it, how much was wilderness and how much was mythical. There are divergent opinions over the extent to which nature influences human affairs, some taking the position of limited environmental determinism, others insisting that culture determines all. Worster believes in straddling both worlds by asserting that the cultural history of nature is as significant as the ecological history of culture. In considering how the field has developed historians have given a prime role to the workings of nature independent of human actions while at the same time continuing to place more of an emphasis on human interactions with the rural and nonarable environment. As Caroline Ford had argued many of the recent studies in environmental history stress the blurred aspect of the nature–culture divide. This article attempts to explore the various themes within colonial environmental history by examining the work of some of its practitioners.

Themes and Contexts in Colonial Environmental History

Environmental history, then, seeks to address the lacunae of the absence of nature in the study of history by developing new perspectives on the historian's enterprise. In histories of the empire, for example, this absence is particularly marked considering the fact, as Richard Grove argues, that the development of an environmental sensibility can be traced to the encounter of seventeenth and eighteenth century western Europeans, especially naturalists, medical officers and administrators with the startlingly unfamiliar environments of the tropics and with the damage done to these environments by them. Thus in Grove's work this unnatural history of the empire has been revised and the growing domain of environmental history has taken root in studies of the empire. Both Grove and Worster argued strongly for the need to think globally about environmental history. Donald Worster notes that one needs 'to take an all inclusive view to study the planet as a single integrated system that has been radically reorganized by a single, integrated economy, technology and culture … a point in history when people on every continent began to experience the same reality…and to satisfy their personal needs by drawing bon the most remote parts of the earth.' He notes that it is not easy to put precise dates on that era, which is still incomplete, but we should acknowledge as foundational the discovery of the western hemisphere, the invention of new communication and transportation technologies, and the appearance of worldwide markets. At its core, global environmental history must deal with capitalism as the pioneering, and still the most important, architect of that new integrated world economy.

As a discipline, Environmental history seems to have originated in Europe and America in part as an offshoot of the postwar wave of environmentalism which first made itself felt in the 1960s in Europe and America. Rachel Carson's *The Sea around us* (1952) and *Silent Spring* (1962) were a clarion call not just for new environmentalism but for environmental history. In 1967, there appeared another volume of quite extraordinary breadth and depth, Clarence Glacken's, *Traces on the Rhodian shore*. This book really marks a transition between historical geography and environmental history, although in some respects it is a unique study in the history of environmental and cultural change. The 1970s saw the growing strength of environmental history in the US with publications of books by authors such as Roderick Nash, Alfred Crosby and Donald Worster. By the 1980s and 1990s other books followed notably by Richard Grove, Carolyn Merchant, William Cronon, Donald Hughes and John McNeill. Most of the reviews of environmental history argue that the discipline was most firmly rooted in the US and had only a limited following elsewhere including

in Europe. However Grove's pioneering work has attempted to shift the discussion away from the American debates seeking instead to uncover the historiography of environmental history which he believed developed in the colonial tropics in the context of the Dutch, French, and English maritime empires. I shall discuss in this article specifically about Worster's and Grove's studies, which are a useful background to world environmental history and self consciously have carved out the field of environmental history and global environmental history. As Worster has recently noted, 'To think globally about environmental history means transcending national boundaries or local concerns that today bind all peoples and all ecosystems together and to understand how that happened and what the consequences have been.'

Worster's early work *Nature's Economy* traced the history of ecological ideas from Gilbert White, who wrote the *Natural History of Selbourne* in 1789 to Linnaeus whose essay 'The Oeconomy of Nature' in 1749 became the single most important summary of the world ecological point of view still in its infancy. Man and his ambitions in the natural economy are an integral part of the Linnaean model, and occupy a special place of dignity and honor.

> All these treasures of nature, so artfully contrived, so wonderfully propagated, so providentially supported through her three kingdoms, seem intended by the creator for the sake of man. Everything may be made subservient to his use; if not immediately, yet mediately, not so to that of other animals. By the help of reason man tames the fiercest animals, pursues and catches the swiftest, nay he is able to reach even those, which lie hidden in the bottom of the sea.

Worster then moves on to look at Thoreau and Charles Darwin. For Darwin the discovery of the Galápagos Islands introduced a counternarrative to the Arcadian vision of Gilbert White and Thoreau. In the Argentine pampas, especially along the La Plata river, the arrival of a European population with its domestic stock had worked disaster on the aboriginal order of nature. 'The countless herds of horses, cattle and sheep,' not only have altered the whole aspect of the vegetation, but they have banished the guanaco, deer and ostrich,' he wrote. Darwin had enough evidence to believe that the present order of animals was by no means the first to live on this land, and that death was as possible for a whole ecological system as it was for any of its members. Such a realizaion made its contribution to Darwin's awareness of the potent forces arrayed against the living. Extinction and conflict were far from the qualities of Arcadia. Wherever he turned he saw the 'universal signs of violence' Among Darwin's chief guides were Lyell's *Principles of Geology* published 1830 and Alexander Von Humboldt's *Personal Narrative* of 1807, a pioneering work, one might argue, in ecological biology. This is all very informative and interesting. However what Worster fails to point out is that perhaps most important among the 16 major books which Darwin carried with him on the Beagle was that by Alexander Beatson, an Indian army engineer who published *Tracts Relative to the Island of St Helena* in 1816. This book included a listing by William Roxburgh of the endemic plants of St Helena Island and comments on their rates of extinction. This became vital in the construction of Darwin's theory of natural selection.

So too, Worster in attempting to examine the origins of ecology, looks exclusively at the Anglo-American world, neglecting the development of understandings about man and nature in the tropical world. To understand this we have to look at the work of Richard Grove in the 1980s and 1990s and to his pioneering work in locating the emergence of a unique environmental awareness, not in the metropolitan center but in the colonial periphery from a very early period. Much of this awareness was based on the development of climatic anxieties. Indeed world environmental history is today increasingly concerned with the historical impact of global climatic anomalies, a major theme in Grove's work, which I now want to discuss.

In *Green Imperialism*, Grove argues that the emergence of a truly global environmental awareness was a very specific historical development. It depended on new empirical knowledge of the scale of the world and actual observations of human ability to change the natural environment on a global basis. Global environmental awareness was thus directly connected to a new capacity for people to travel large distances, transform the earth, and acquire knowledge about the environment. Two elements were necessary for this awareness to emerge: first, the institution of capital and shareholder-rich maritime trading companies backed by state legislation and assistance; and second, the settlement of previously uninhabited islands and continental peninsulas in the tropics and subtropics by colonial settlers and planters. The profit motives and mechanisms of these trading companies, especially of the East India Companies of Portugal, the Netherlands, Britain, and France, resulted in intensive cash-crop plantation activities on oceanic islands and the clearing of forests for agriculture, fuel wood and ship construction.

This process had already begun with Portuguese and Spanish settlement and plantation agriculture on the Azores, Canaries, and Madeira Islands during the fourteenth century, but the sheer scale of its impact was massively expanded as the European trading companies developed their routes to India, the East Indies, and the Caribbean. As early as the 1670s, the catastrophic consequences of their capital- and labor-intensive activities became clear as the early island colonies experienced drought due to the drying up of perennial streams, soil erosion, dust storms, and the disappearance of animal and plant species. These developments all made practical survival on oceanic islands difficult and encouraged wider questions about the sustainability of a confined settlement. Islands soon became symbolic of the explored world and encouraged ideas about limited resources and the need for conservation or sustainability. (The idea of regional environmental degradation or control was not new; indeed the word 'conservancy' was first adopted in Britain in the 14th century with relation to the control of whole river basins, such as that of the Thames river. Similarly, in the Venetian Republic, well-developed ideas existed about the control of deforestation in the hills in order to control erosion and silting downstream. These initiatives may have been early signs of responses by new, highly sophisticated maritime states to the first consequences of early merchant capitalism and trade that had a global reach. Indeed, even before the advent of large continental-based European empires in Asia, Africa, and the Americas, the scale of artificially caused environmental change

was already being transformed as European maritime countries started to exploit new kinds of natural resources on a global scale. Sugar and other crops essential to the new urban markets of Europe were cultivated on small islands, especially in the West Indies, Indian Ocean, and East Indies. After about 1400, fisheries extended to an oceanic scale as seals and whales were hunted from pole to pole. See Grove, *Green Imperialism, Colonial Expansion, Tropical Island Edens and the Origins of Environmentalism, 1600–1800*.)

The extension of what Immanuel Wallerstein has called the capitalist "world system" on a global scale between 1200 and 1788 had a critically important dimension in terms of resource exploitation. European merchants and companies found that they could exploit the trade goods, markets, and resources of almost every land, in what became an expanding commodity frontier, the "unending frontier" in the title of John Richards important recent book on the environmental history of the early modern world. However, capitalist accumulation and trade developed quite autonomously in South and East Asia, something Wallerstein was really unable to incorporate in his global theory. But in the centers of indigenous capital too, major transformations of the natural landscape took place. Some, like the deforestation of the Ganga basin, had already been long in progress, but they were quickly accelerated after 1400 as powerful mercantile empires developed. However, it was in the tropics that the destructive environmental impact of globalization made its most obvious impact to the observer. One of the first symptoms of the early phases of globalization was the marginalization, enslavement, and then extinction of small indigenous cultures, especially those of island peoples; the indigenes of the Canary Islands are a classic example. However, it was on uninhabited islands such as St. Helena and Mauritius that the full effects of highly capitalized plantations, forest clearance, and import of alien animals (especially pigs, goats, and rats) were first observed. The extinction of the dodo made a great impression on contemporary naturalists. The fact that oceanic islands were perceived as highly desirable 'Edenic' locations in long-running European cultural traditions served to emphasize the shock of their manifest and rapid degradation. Moreover, their degradation threatened their role as watering and supply stations for company ships. In these circumstances, the colonial governments of many small islands became environmentalist, if only to ensure their own survival and that of their agricultural settlers and slaves.

It is possible to argue that early environmental inquiry seems to have been driven by neo-Malthusian concerns about the possible demise of civilization as a result of the 'limits to growth.' A parallel concern is the discussion of the historical collapse of previous societies linked to apparent resource exhaustion and the failure of institutions to adapt to looming crises in time to prevent disaster. The classic discussion is the debate about Easter Island and the fate of its population doomed by deforestation and overfishing. Neo-Malthusian ghosts haunt the discussion of resource shortages and the failure of adaptation on the part of many societies for example in the recent work of Jared Diamond, *Collapse*. But it is worth noting that the theme of collapse also haunts European history, Environmental matters have been more fundamental to imperial politics than is usually understood. In Richard Grove's terms, colonial ecological interventions, especially in deforestation and subsequently in forest conservation, irrigation and soil 'protection,' exercised a far more profound influence over most people than the more conspicuous and dramatic aspects of colonial rule that have traditionally preoccupied historians. Over the period 1670 to 1950, very approximately, a pattern of ecological power relations emerged in which the expanding European states acquired a global reach over natural resources in terms of consumption and then too, in terms of political and ecological control. The reasons for this are not very complicated, but they need restating more frequently than has been the practice in most discussions of environment.

The argument presented by Grove about the expanding resource frontier of Europe has also been replicated by other environmental historians notably by Alfred Crosby in *Ecological Imperialism* where he argues that the process of imperial expansion, whether in terms of direct conquest in what Crosby calls the neo-Europes, or indirect disruptions as a consequences of trading patterns and military actions, fundamentally changed many ecological processes. The introduction of horses to the Americas, rabbits to Australia, or even the humble potato from the Americas to Europe, changed the environments of these places. This is not the first time such changes had altered the planet's ecology; the emergence of agriculture and the domestication of animals has meant that the Holocene, the geological period since the last glacial episode, has been one of anthropogenic-induced changes in most places, but the accelerating speed and scale of change in the last half millennium is what is most important. The ecological dimension of such imperialism is what needs much more attention than it has received until relatively recently. However, Crosby focuses exclusively on the white settler colonies and omits any discussion of the much extensive regions of the colonial tropics. In Grove's terms, the focus on the political and the administrative dimensions of empire have occluded the practical material impacts of colonization on people's lives and on land, animals, fish, forests and other facets of their ecological contexts. The environment has, in these terms, simply been taken for granted until recently when the ecological dimension of human history, minus the distractions of environmental determinism, is once again being worked into the picture.

Grove argues for example, that the Caribbean and its littoral, along with Bermuda, has been a very important area for working out the processes going on in world environmental history in the context of European economic expansion and globalization. Some of the first comprehensive forest-protection legislation on such colonies was introduced after 1620 in Bermuda and a little later in the Caribbean Leeward Islands. In Montserrat, the mountain forests of the island were protected from felling after 1702 by a rigid ordinance, with the knowledge that unrestricted logging caused soil erosion and flooding on lower grounds and in towns. The Caribbean islands, with their large settler and slave populations, came under sustained ecological pressure at an early date and, as on Mauritius and St. Helena, awareness quickly grew of the physical changes and extinctions brought about by commercial clearance. As early as 1616, measures had been taken to protect the indigenous edible sea birds in Bermuda. By the mid-eighteenth century, overfishing and major reductions in catches were taking place around many now

densely populated islands. Other legislation followed making conservation an integral part of colonial landscape control. Before the 1760s, the effects of colonial economic globalization were addressed on a piecemeal basis in order to protect local food, fuel, timber supplies, and what were already recognized as rare island species. However, in the mid-1760s, responses to deforestation in particular suddenly changed. This was due to the rapid spread of a theory first enunciated in France by Pierre Poivre that linked deforestation to rainfall and regional climate change. In the ensuing century, forest-reserve legislation responding to fears of deforestation-induced climate change slowly began to spread around the world, especially throughout the French, British, and Dutch empires. By the late 1830s and the 1840s, the reiteration of climatic environmentalism by Alexander von Humboldt and Jean-Baptiste Boussingault was being acted upon by environmentally minded scientists and officials working not just only on the islands but also on the large land masses of India, Southeast Asia, Southern Africa, and Australia, where the demands of European colonial empires were now bringing about deforestation at an unprecedented speed. It is to these specifics that we will now turn. The context is the growing discussion of the environment by scientists, travellers and administrators in the context of empire in the nineteenth century.

Early Colonial Scientists, Environmentalism and Environmental History

It is no accident that the earliest writers to comment specifically on rapid environmental change in the context of empires were scientists who were themselves often actors in the process of colonially stimulated environmental change. In a study, Grove and Damodaran have argued that the early pioneers of an environmental critique of the European and American empires depended on having an historical perception of rapid rates of ecological change, and access to evidence for rapid change. As early as the mid-seventeenth century we find that intellectuals and natural philosophers such as Richard Norwood and William Sayle in Bermuda, Thomas Tryon in Barbados and Edmond Halley and Isaac Pyke on St Helena were all already well aware of characteristically high rates of soil erosion and deforestation in the colonial tropics, and of the urgent need for conservationist intervention especially to protect forests and threatened species.

On French colonial Mauritius (the Isle de France) Pierre Poivre and Philibert Commerson framed pioneering forest conservation legislation designed specifically to prevent rainfall decline in the 1760s. In India William Roxburgh, Edward Balfour, Alexander Gibson and Hugh Cleghorn (all Scottish medical scientists) wrote alarmist narratives relating deforestation to the danger of climate change. Their distinctively modern environmentalist views owed a great deal to the precocious commentaries of Alexander von Humboldt in his *Personal Narrative* and in the *Cosmos*. East India Company scientists were also well aware of French experience in trying to prevent deforestation and rainfall change in Mauritius. William Roxburgh, together with Alexander Beatson on St Helena, went on further to observe the incidence of global drought events which we know today were globally teleconnected El Nino events. The rise of imperial networks of information thus enabled the emergence of a new global environmental awareness as well as the first accurate accounts of global change.

The writings of Edward Balfour and Hugh Cleghorn in the late 1840s in particular illustrate the extent of the permeation of a global environmental consciousness and could be said to constitute some of the first writings in world environmental history. In very similar fashion Baron Ferdinand Von Mueller in Australia, George Perkins Marsh and Franklin Benjamin Hough in the United States and John Croumbie Brown in South Africa all wrote multiple and voluminous texts that display formidable textual knowledge of evidence of global environmental change through time, which was used by all these men as material to warn of the dangers of future environmental profligacy and global ruin. It is significant that most of these men published their most important texts during the 1860s, a period which we could appropriately name the 'first environmental decade,' and which embodies a convergence of thinking about ecological change on a world scale that may well have been permeated in part by ontological and existential concerns elicited by the publication of Charles Darwin's *The Origin of Species* in 1859.

It was in the particular circumstances of environmental change at the colonial periphery that what we would now term 'environmentalism' first made itself felt and its colonial proponents were often in a position to make use of historical evidence for environmental change in government records and thus became *de facto* environmental historians. Victorian texts such as Strzelecki's *Physical Description of New South Wales*, Berthold von Ribbentrop's *Forestry in the British Empire*, Brown's *Hydrology of South Africa*, Cleghorn's *Forests and Gardens of South India* and Marsh's *Man and Nature* were not only vital to the onset of environmentalism; they were also meticulously documented works in environmental history. One preoccupation stands out in them above all. This was a growing interest in the potential human impact on climate change, in particular a fear that human activity, especially deforestation, might lead to global desiccation. This fear grew steadily in the wake of colonial expansion and fed into postcolonial fears about desertification articulated by international bodies and global nongovernmental organizations (NGOs). It also critically affected the early direction of environmental history. The preoccupation with climate probably owed much of its strength to notions linking climate, civilizational degeneration and racial types. Many of these notions had first been formally articulated by the Comte de Buffon.

Particularly after the 1860s, and even more after the great Indian famines of 1876- and 1899–1902, these connections encouraged and stimulated the idea that human history and environmental change might be firmly linked. The years immediately prior to 1900 saw a renewed interest developing in what were essentially millennial theories of global desiccation closely related to contemporary convictions about the 'inevitable' extinctions of both indigenous people and large tropical mammals such as the African Elephant. These theories were reinforced by climatic events. By the end of the nineteenth century it was evident that short-term vicissitudes of the African climate were of considerable economic importance. In East Africa the level of Lake Victoria rose suddenly in 1878 after unusually heavy rains. A few months later there was abundant

rain over the Blue Nile's catchment in Ethiopia and disastrous Nile floods followed in Egypt. In Southern Africa in 1862 and between 1881 and 1885 there were severe droughts. Alexander Knox in *The Climate of the Continent of Africa* (1911) pointed to what he saw as a decline in the rainfall of nineteenth century Senegal. The mean at St Louis in the 1830s had been about 600 mm; over the years 1892–1905 it was about 400 mm; in 1903 it was only 125 mm. Over the next decade rainfall was greater in Senegal and the rest of the Sudano-Sahelian but in 1913 there came a drought disaster, the terrible results of famine in Northern Nigeria that year being graphically described by Hastings in *Nigerian Days*. In Egypt the flow of the Nile was phenomenally low, and in Southern Africa there was widespread drought.

During the same period a number of American geographers started to pose a postglacial desiccation of the environments of central Asia and China based on the twin tenets that wet conditions characterized the glacial phases of the Pleistocene and that aridity had increased since the warming of the Pleistocene icesheets in the Holocene. Travellers in central Asia pointed to the occurrence of dry water courses and lakes and abandoned settlements as evidence of this desiccation and suggested that deteriorating environmental conditions had spurred successive nomadic invasions of their more civilized neighbors during periods of increased aridity. A major early exemplar of this group of scholar-travellers was an American, Ellsworth Huntington, a geographer and environmental determinist whose views were formed by his travels and intelligence activities in Central Asia. His first major work, *The Pulse of Asia* (1907) set an agenda for both desiccationism and environmental determinism. Both Huntington and Kropotkin (the latter in a landmark article published in *The Geographical Journal* in 1904) were critically influenced by the rise of contemporary anxieties in the tropics and a growing interest in climatic interpretations of history, boosted by the great Indian famines of the late nineteenth century. While at Harvard, Huntington had been a pupil of William Morris Davis at a time when the latter had been developing his theories of evolutionary landscape geomorphology. Huntington was, together with Andrew Douglass, one of the first practitioners of dendrochronology. They pioneered the use of this new dating technique on the Sequoia trees of California, whose immense age made a great impression on Huntington. But his formative experiences were in Turkey, where he taught at Euphrates College in 1897–1901 and in Turkestan. After Harvard, Huntington accompanied William Davis on the Pumpelly (1903) to Turkestan and then went with Barrett's (1905–6) expeditions to central Asia.

Colonial Environmental Ideas in the Twentieth Century

Throughout the 1920s and 1930s the experience of central Asia, which had exerted so much influence on Huntington, continued to exert an influence on the desiccationist school. The Chinese meteorologist Coching Chu, in 1926, summarized much of this in a paper on 'Climatic pulsations during historic times in China' Geographical periodicals and institutions were, as in the previous century, important as fora for the desiccation debate. In Africa this meant that the concerns of the 1920s now began to embrace some colonial territories that had not featured at all in the earlier environmental literature of the years before the Great War, but which were now the subject of considerable colonial interest and infrastructure investment. In the 1920s the Colonial Office was the main employer of British biologists, geologists and geographers. This was especially the case in Anglo-Egyptian Sudan, about which some of the first literature on desert-spreading or desertification now began to be written. A pioneer in this area was E.W. Bovill, who echoed Schwartz in South Africa in his 1921 paper on 'the encroachment of the Sahara on the Sudan.' His arguments were further followed up in an article entitled 'Sahara' in 1929 Bovill's articles were in turn taken much further by G.T. Renner in one of the first articles to paint Africa as a potentially famine-ridden continent, under the title 'A famine zone in Africa; the Sudan,' published in 1926. A widespread semiarid region meant that a disproportionately large alarmist South African literature developed on environmental matters. Prominent among these was the 1926 work by J.C. Smuts on *Holism and Evolution*, a work heavily influenced by the ecological theories of Arthur Tansley.

The emergence of a period of environmental alarmism in North America consequent on the prolonged 'dustbowl' droughts in the southern United States in the early 1930s supplemented the existing colonial panic over desert-spreading. This increased local anxieties and affected policy in some British and French colonies. Thus the New Deal conservationism of the United States was emulated particularly in the east and central African colonies. Soil erosion had already become a prominent issue in India during the period 1890–1925 and huge investments to control it were made, for example, in the Etawah region of the United Provinces of northern India. These efforts, like similar measures in West and South Africa, long predated the American 'Dustbowl' alarmism. In 1934 E.P. Stebbing, a very prominent Indian forester, and onetime Professor of Forestry at Edinburgh University, visited West Africa. Stebbing was the earliest historian of Indian forests and by the time of his visit has already published a three volume work on *The forests of India*, much of which detailed the history of environmental concern and early conservationism among the first surgeon-foresters of the East India Company medical service. His short visit to the French and British West African colonies, made significantly during the dry season, provoked him into writing a feverish warning on what he saw as the dangers of desert-spreading. The title of this essay 'The encroaching Sahara; the threat to the West African colonies' indicates that he had almost certainly read Bovill's similarly titled 1921 article on 'The encroachment of the Sahara.'

While Stebbing's somewhat hysterical warnings were downplayed by local colonial scientists, who had much greater experience of the causes, rates and seasonality of local desertification and erosion, his terminology was taken up with alacrity by governing circles in Paris and London. Stebbing's writings led directly to the founding of the Anglo-French Boundary Forest Commission. This commission, started in 1934, soon found that Stebbing's warnings were largely unjustified, and his analysis was decisively dismissed by B. Jones, a member of the commission, in an article published, as Stebbing's had been, in *The Geographical Journal*.

Notwithstanding, in 1937 Stebbing, now Professor of Forestry in Edinburgh, pursued his concerns in *Forestry in West Africa and the Sahara; a Study of Modern Conditions* and in an inflammatory work called *The Creeping Desert in the Sudan and Elsewhere in Africa*. He was not alone. In 1938 Francis Ratcliffe, fresh from his investigations of the causes of soil erosion in South Australia and Queensland, published *Flying Fox and Drifting Sand*, a savage indictment of the impact of extensive outback agriculture, and the first of a long line of apocalyptic books on the degradation of the Australian environment, many of which exercised a disproportionate influence on global environmental concerns far outside the antipodean context. Ratcliffe was familiar with the writings of Keith Hancock, later a prominent historian of the British Empire and Commonwealth, who in 1931 had published a virulent attack on profligate deforestation and land-clearing by settlers Hancock, a Quaker, was the biographer of Jan Smuts and was undoubtedly influenced by the 'holistic' views of the latter, not least in his role as an early environmental campaigner and environmental historian. Both men were profoundly interested in the historical impact of white colonial settlement on indigenous peoples and their environments at an imperial and world scale, Hancock ultimately writing on this theme in what was one of the earliest and most influential texts in Australian environmental history. In Hancock's mind the two world wars, Nazi death camps and the ecological crisis were linked catastrophes in a personal existential crisis which was partially expressed in his writing of environmental history.

In 1938 Gordon East published the first of many editions of *The Geography behind History*, a wide-ranging work which echoed many of the contemporary colonial anxieties albeit in a rather more detached and academic mode. Thus by 1938 the global environmentalist ball had truly started to roll, propelled largely by colonial exemplars and Stebbing's alarums, along with comparable simultaneous warnings from the United States which were soon being echoed by a cacophony of popular writers and journalists and above all by Graham Jacks and R.O. Whyte in their inflammatory, semi-racist and highly colored account book of 1939 entitled *The Rape of the Earth; a World Survey of Soil Erosion*. This book skillfully marshaled evidence for the kind of rapid environmental change which had been predicted by John Croumbie Brown and G.P. Marsh 70 years earlier, but referring to world-wide evidence of a detail which they had not been in a position to compile. The book set the scene for the postwar British (and French) colonial obsession with soil erosion and gullying in their postwar 'second colonial occupations,' as well as for the global desertification mania which developed in the 1970s in the wake of major droughts in West Africa. Conceivably, *The Rape of the Earth* owed some of its impact to underlying political anxieties in Britain, France, and the United States about the growing threat now posed by fascist regimes and above all by Nazi Germany both on the domestic and colonial front. Environmental fears were, conceivably, more palatable and thus easier to articulate and confront.

These agendas of colonial environmental thinking had taken over academic debate by the 1930s. Once the discipline of environmental history began to establish itself as a separately defined field of scholarship in the 1970s, these early ideas continued to fuel academic thinking. Grove's work seized the initiative for early environmental scholarship away from the American academy where practitioners believed it to be most deeply rooted to the colonial context of the tropics. Colonial environmental thinking he argued had an important impact on the emergence of the field.

More recently the story of colonial environmental history has developed in different ways. For example in South Asia, a shift toward an ecological questioning of conventional agrarian history developed among historians of South Asia in the early 1980s, and particularly in the minds of Richard Tucker and John Richards, the latter being a specialist in the monetary and agrarian history of Mughal India. Both men were convinced that ecological changes accompanying economic transition in the seventeenth to nineteenth centuries, while clearly large-scale, had never been properly quantified. Almost immediately Richards and Tucker, working in tandem, realized that their questioning could not be confined to South Asia but was equally requiring of answers researched in terms of global economic history in general, particularly with the advent of an era in which the connections between deforestation, carbon dioxide production, and global warming were becoming major popular anxieties in what Teresa Brennan was already calling the 'Age of Paranoia.' In two major edited works they therefore set out to review the global history of deforestation, especially in the tropics. However, in making the quick and logical intellectual leap from South Asia to world history, Richards and Tucker had ironically left the environmental history of South Asia itself largely undone with the exception of some very limited essays, regional studies, and essay collections. This is now being redressed in several recent studies on the environmental history of South Asia. In particular, the work of K. Sivaramakrishnan, Mahesh Rangarajan, Ravi Rajan, Rohan D'Souza, Vasant Saberwal, Dhirendra Dangwal. Not only have these works made a substantial presence in mainstream South Asian history writing but in terms of institutional advance as well. As D'souza notes 'these studies have propelled the South Asian experience to the centerstage of the field of environmental writing.' In some respects the early work in Indian environmental history resembled that in the Americas and Africa, positing an ecological golden age but more recent work is starting to challenge this notion.

Landscape Imagery and Colonial Environmental History

Another burgeoning trend in colonial environmental history is in landscape imagery and construction, which builds on the work in the 1980s and 1990s of Paul Carter, Simon Schama, Denis Cosgrove, and Steve Daniel. In the colonial context, the recent work of Graham Burnett, Matthew Edney, and David Arnold explores the culture of the tropics in implicitly rejecting the nature–culture dualism and blurring the boundaries. This is particularly true of David Arnold's work, *The Tropics and the Traveling Gaze* which examines the invention of the tropics from the eighteenth century. The eighteenth century was inter alia, an age of decorative gardens and of gardeners. One of England's more notable contributions to the neoclassical movement was the landscape garden in which the formal, regular, and ostentatious shapes of the baroque era were swept

away to be replaced with no-less cultivated, but naturalistic landscapes complemented by artificial lakes and classical ruins blended into the surroundings. The picturesque landscape of Capability Brown and Humphrey Repton are examples of these. But, as Addison noted:

> Why may not a whole estate be thrown into a kind of garden by frequent plantations, which may turn as much to the profit as the pleasure of the owner?

The search for more exotic decorative plants was intensified in the new era of exploration as evident from David Mackay's work (*In the Wake of Cook: Exploration, Science and Empire, 1780–1801*, 1985). Eventually, with the voyages of Bougainville and Cook, the Arcadian quest encompassed the south Pacific. The perception of the tropics that explorers and their artists carried with them was one of a naturalistic landscape with lush forests, steep cliff walls and waterfalls, instead of lakes and temples. A naive and noble savage formed part of the scenery as he sheltered in the romantic grotto from the elemental powers of nature. This romantic prospect frequently conflated the dramatic and the verdant landscape of Tahiti with the real economy of its inhabitants. Incidentally the same notions were transferred to the Indian Ocean islands, an apparently Utopian realm that has been little explored by scholars.

In his magnificent study, *The European Vision and the South Pacific* Bernard Smith has shown how exotic topography was elevated to high places reserved for ideal landscapes by the late eighteenth century, and underlines the significance of the fact that the term picturesque was being used to embrace the growing interest in the exotic. As a tradition conceived by Uvedale Price in 1794, the picturesque was perceived as an aesthetic category distinct from the Burkean notion of the sublime and the beautiful; it was distinguished by roughness, sudden variation and irregularity. While artists like William Hodges still sought to make the tropical landscape conform to the taste of their time by adapting it to the Italianate landscape there was an emerging perception in the late eighteenth century among philosophers and writers such as von Humboldt that the noblest landscapes were to be found in the tropics.

This burgeoning interest in landscape imagery and construction, some of which fed into environmental history, explicitly uses Saidian notions. For example in Burnett's work entitled *Masters of All They Surveyed*, on the exploration of British Guyana in the nineteenth century argues that colonial constructions of landmarks became not only 'places to see, but places that enhanced seeing and a technique for establishing a control over space.' He notes that, like the imperial picturesque of India which was used by British topographical surveyors both as a natural representation of the Indian landscape and as an invitation to British conquest, representations of the Guyanan landscape worked in similar ways. Explorers such as Richard Schomburgk, 'were aware of the power of their images and the processes involved in renaming, landmarking and resource assessment leading to the establishment of colonial boundaries and colonial order.' There are problems with using explicitly Saidian notions for understanding colonial engagements with the landscape. Bernard Smith's story is not one of simple appropriation, control and establishment of order through topographical art, but a story of a much more complex relationship between art and ideas. While between 1750 and 1850, a great deal of artistic talent was brought in to serve the biological and geographical sciences in the colonies a 'vigorous and aesthetically vibrant art movement was beginning to emerge in the context of the exploration of the new worlds.' While depiction of plants and animals within a typical landscape became increasingly common landscape painters were beginning to recognize the fact that the tropical world contained its own distinctive sceneries, which had a visual unity of its own. It was in the paintings of William Hodges that these ideas first began to challenge neoclassical values, but it was through the work of Alexander von Humboldt that this new artistic movement was celebrated, influencing such writers and artists as Gustav Carus and John Ruskin and in a circular sense, reinvigorating artistic and environmental sensibilities in Europe. Tim Bonyhady's (2000) book, entitled *The Colonial Earth*, a superb essay on the development of environmentalism in pre-1900 Australia, contains an excellent analysis of this development of independent colonial sensibilities, especially in connection with the work of the painter Eugene von Guerard.

Although what was termed 'nature's wild garden' by the Romantics had its effects on Sir Joseph Banks when he traveled with Cook, the sort of gardens in which he was interested by the 1780s was largely botanic ones. At Kew, Chelsea, and Edinburgh, men were trained in the empirical processes of observation, comparison and evaluation, and they began to gather comprehensive collections of native and exotic plants for microscopic examination. Drawing on the pioneer work in plant classification carried out by Linneaus, Britain despatched plant collectors to every corner of the globe, and these men sent home living plant specimens, seeds and dried samples to their patrons and employers. As early as the seventeenth century in Malabar, the botanist and traveler Van Reede moved further away from European precepts to a wholly Malayali classification of plants. Van Reede's reliance on local informants and his frequent contacts with Tiya and Ezhava 'low-caste' plant collectors helped to incorporate local Ezhavas botanical knowledge into the *Hortus Malabaricus Indicus*. This gigantic twelve-volume work which adhered religiously to local systems of plant classification and which rejected both Arabic classification and nomenclature and Brahminical systems, as well as European knowledge, all of which had proved virtually useless to the realities of plant identification and systematic knowledge as far as the Dutch were concerned. The extraordinary utility of the indigenous Malabar plant knowledge systems and systems of classification as compiled by Van Rheede and Itti Achuden, his main informant, were explicitly and remarkably recognized by Linnaeus. Indeed Linnaeus simply incorporated the Ezhava classification system wholesale, and without changes, when he came to describe the tropical plants of South India.

From the middle of the eighteenth century onwards the utilitarian strain in natural history became more pronounced as scientists and collectors interested themselves in the practical benefits which might be reaped from their endeavors. In many respects, it was thought, the world of nature had not endowed equally the peoples of the earth. Botanists in particular believed that their technical skills would enable them to rectify the imbalance by transferring certain natural productions from one region to another, and acclimatizing them in

the new environment. Periodic famines in India, for example, could be averted by planting Sago or other drought-resistant crops. English cotton mills might be supplied with raw cotton from improved seeds, while transplanted flax could provide cheap fibers. Above all, attempts were made to transplant spice and pepper species into new territories where they were previously unknown.

Such schemes had the mercantilist purpose of destroying the monopolies or predominance of rival nations and colonies and substituting that of another. Particular efforts were made by the French and British to break the Dutch spice monopolies in the East Indies. Botany and great power rivalry became intertwined as nations endeavored to guard their precious treasures. It was in this context that Captain Bligh's expedition took place. The story of Sir Joseph Banks, breadfruit and Tahiti is well known. Less well known is that it stimulated the advent of forest protection in the West Indies, just as spice transplantation to Mauritius had stimulated forest preservation there during the ancient regime.

However most of the studies of the culture of the landscape in the context of empire are about the colonization of space and how landscapes gain a moral and even redemptive significance. Some of it is a postmodern interpretation of landscape imagery and of the landscape as a cultural text. In doing so, writers such as Arnold uses a range of sources mainly Paul Carter, Michel Foucault and Bernard Cohn to see the environment as socially constructed and to suggest the idea that the 'tropics were invented as much as they were encountered' for example by the British in India in the nineteenth century. The idea of the tropics as 'warm, fecund, luxuriant, paradisical and pestilential' was central to the constitution of British colonial knowledge and was a critical ingredient in the larger colonizing process.

Thus we can see that environmental history allows for divergent opinions over the extent to which nature influences human affairs, some taking the position of limited environmental determinism, others insisting that culture determines all. While Crosby, Grove and Diamond fall into the former category, Arnold, Carter, Cosgrove and Daniels fall into the latter. Worster's point about straddling both worlds by asserting that the cultural history of nature is as significant as the ecological history of culture is a pertinent one and gives us new ways of understanding the history of European intervention in the tropical world. This article has attempted to explore the historiography of tropical environmental history which can now claim to be an important subfield within the discipline of environmental history. As John Mcneill has noted 'interest in environmental history depends, in large part, on anxiety about contemporary social problems.' (John Mcneill, 'Observations on the nature and culture of environmental history, *History and Theory*, 42, 2003.) With ecological concerns increasing environmental history and especially tropical environmental history is a burgeoning and innovative field of interest.

Environmental Justice in the United States

Robert D Bullard, Texas Southern University, Houston, TX, USA

Abstract

Despite significant improvements in environmental protection over the past several decades, millions of Americans continue to live in unsafe and unhealthy physical environments. Many economically impoverished and politically powerless individuals are exposed to greater health hazards in their homes, on the jobs, and in their neighborhoods when compared to their more affluent counterparts. A growing body of evidence reveals that people of color and low-income persons have borne greater environmental and health risks than society at large. Over the last two decades, grassroots activists in the United Staes have attempted to change the way government implements environmental, health, and civil rights laws. These groups have also organized, educated, and empowered themselves to make government and industry responsive to their needs.

Introduction

Numerous studies reveal that low-income persons and people of color have borne greater health and environmental risk burdens than the society at large. Environmental justice is defined as the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. Fair treatment means that no group of people, including racial, ethnic, or socioeconomic groups should bear a disproportionate share of the negative environmental consequences resulting from industrial, municipal, and commercial operations or the execution of federal, state, local, and tribal programs, and policies. The grassroots environmental justice movement challenged the dominant environmental protection paradigm – a framework that manages, regulates, and distributes risks. On the other hand, the environmental justice paradigm embraces a holistic approach to formulating health policies and regulations, developing risk reduction strategies for multiple, cumulative and synergistic risks, ensuring public health, enhancing of public participation in environmental decision-making, promoting community empowerment, building infrastructure for achieving environmental justice and sustainable communities, ensuring interagency cooperation and coordination, developing innovative public/private partnerships and collaboratives, enhancing community-based pollution prevention strategies, ensuring community-based sustainable economic development, and developing geographically oriented community-wide programming.

Despite significant improvements in environmental protection over the four decades, millions of Americans continue to live in unsafe and unhealthy physical environments. Hardly a day passes without the media discovering some community or neighborhood fighting a landfill, incinerator, chemical plant, or some other polluting industry. This was not always the case. In the 1970s, the concept of environmental justice had not registered on the radar screens of environmental, civil rights, or social justice groups. Nevertheless, it should not be forgotten that Dr Martin Luther King, Jr. went to Memphis in 1968 on an environmental and economic justice mission for the striking black garbage workers. The strikers were demanding equal pay and better working condition. Of course, Dr King was assassinated before he could complete his mission.

Birth of a New Movement

The national environmental justice movement emerged around the issues of fairness, social equity, and environmental protection. This new movement embraces the principle that all communities are entitled to equal protection and enforcement of environmental, health, employment, housing, transportation, and civil rights laws and regulations that impact quality of life. The environmental justice framework rests on developing tools and strategies to eliminate unfair, unjust, and inequitable conditions and decisions. The framework also attempts to uncover the underlying assumptions that may contribute to and produce differential exposure and unequal protection. It brings to the surface the *ethical* and *political* questions of 'who gets what, when, why, and how much' (Bullard, 1996). The national environmental justice movement/framework has its origins in the United States of America. In America, low income and people of color communities are disproportionately affected by toxic waste facilities and dirty industries; as well as, internationally where hazardous wastes move from Organization for Economic Co-operation and Development (OECD) states to non-OECD states (Bullard and Johnson, 2000).

Early Struggles

Another landmark garbage dispute took place in Houston, Texas, a decade after the Memphis garbage strike. African-American homeowners in Houston began a bitter fight to keep the Whispering Pines sanitary landfill out of their suburban middle-income neighborhood. The residents formed the Northeast Community Action Group (NECAG). In 1979, NECAG and their attorney, Linda McKeever Bullard, filed a class action lawsuit to block the garbage facility from being built. The 1979 lawsuit, *Bean versus Southwestern Waste*

Management Corp., was the first of its kind to challenge the siting of a waste facility under civil rights law.

The landmark Houston case occurred 3 years before the environmental justice movement was catapulted into the national limelight in the rural and mostly African-American Warren County, North Carolina. The environmental justice movement has come a long ways since its humble beginning in Warren County where a hazardous-waste landfill ignited protests and over 500 arrests. This marked the first time Americans had been arrested protesting the siting of a waste facility.

The Warren County protests provided the impetus for US General Accounting Office to conduct an independent investigation. That study revealed that three out of four of the off-site, commercial hazardous waste landfills in Region 4 (which comprises eight states in the south) were located in predominantly African-American communities, although African-Americans made up only 20% of the region's population (US General Accounting Office, 1983).

After waiting more than two decades, victory finally came to the residents of predominately black Warren County. Since 1982, county residents lived with the legacy of a 142-acre toxic waste dump. Detoxification work began on the dump in June 2001 and the last clean-up work was slated to end the latter part of December 2003. State and federal sources spent $18 million to detoxify or neutralize contaminated soil stored at the Warren County polychlorinated biphenyl (PCB) landfill. A private contractor hired by the state dug up and burned 81 500 tons of oil-laced soil in a kiln that reached more than 800°F to remove the PCBs. The soil was put back in a football-size pit, recovered to form a mound, graded, and seeded with grass.

The protests also led the Commission for Racial Justice (1987) to produce *Toxic Waste and Race*, the first national study to correlate waste facility sites with demographic characteristics. Race was found to be the most potent variable in predicting where these facilities were located – more powerful than poverty, land values, and home ownership or occupancy status. In 2007, the United Church of Christ commissioned a study, 'Toxic Wastes and Race at Twenty 1987–2007,' that chronicles significant environmental justice milestones since 1987 and the report provide a collection of essays from environmental justice leaders on a range of issues (Bullard et al., 2007).

The People of Color Summit

The 1991 First National People of Color Environmental Leadership Summit was probably the most important single event in the young movement's history. Held in Washington, DC, the four-day Summit was attended by over 650 grassroots and national leaders from around the world. Delegates came from all 50 states including Alaska and Hawaii, Puerto Rico, Chile, Mexico, and as far away as the Marshall Islands.

The Summit broadened the environmental justice movement beyond its antitoxics focus and demonstrated that it is possible to build a multiracial grassroots movement around environmental and economic justice. On 27 September 1991, Summit delegates adopted 17 'Principles of Environmental Justice.' By June 1992, Spanish and Portuguese translations of the Principles were being used and circulated by NGOs and environmental justice groups at the Earth Summit and Global Forum in Rio de Janeiro.

In October 2002, the United Church of Christ and environmental justice leaders convened the Second National People of Color Environmental Leadership Summit (Summit II) in Washington, DC. Summit II organizers planned the four-day meeting for 500 participants. However, more than 1400 delegates from grassroots and community-based organizations, faith-based groups, organized labor, civil rights, youth, and academic institutions made their way to the nation's capital to participate in the historic gathering, a clear indication that the movement was alive and well. A special budget was carved out for Summit II youth and student programming. More than three-fourths of Summit II attendees were people of color from community-based organizations and networks.

Government Response

The federal Environmental Protection Agency (EPA) in the United States manages, regulates, and distributes risks. During its 43-year history, the EPA has not always recognized that many government and industry practices (whether intended or unintended) have adverse impact on poor people and people of color. In 1992, after meeting with community leaders, academicians, and civil rights leaders, the EPA (under the Bush Administration) admitted there was a problem, and established the Office of Environmental Equity. The name was changed to the Office of Environmental Justice under the Clinton Administration.

The agency produced *Environmental Equity: Reducing Risks for All Communities*, a comprehensive report that examines environmental justice concerns in low-income and people of color communities (US Environmental Protection Agency, 1992). The EPA also established a 25-member National Environmental Justice Advisory Council (NEJAC) under the Federal Advisory Committee Act. The NEJAC is comprised of stakeholders representing grassroots community groups, environmental groups, nongovernmental organizations, state, local, and tribal governments, academia, and industry.

Environmental Justice Health Symposium

In February 1994, seven federal agencies, including the Agency for Toxic Substances and Disease Registry (ATSDR), National Institute for Environmental Health Sciences, EPA, National Institute of Occupational Safety and Health, National Institutes of Health, Department of Energy, and Centers for Disease Control and Prevention (CDC) sponsored a national health symposium, 'Health and Research Needs to Ensure Environmental Justice.' The February conference was attended by more than 1000 scientists, researchers, health professionals, educators, government officials, and community stakeholders. Scholarships were provided to nearly 300 community leaders.

Environmental justice leaders offered their own environmental protection framework. This framework adopts a public health model of prevention (i.e., elimination of the threat before harm occurs) as the preferred strategy, shifts the burden of proof to polluters/dischargers who do harm, who discriminate, or who do not give equal protection to people of

color, low-income persons, and other 'protected' classes, allows disparate impact and statistical weight or an 'effect' test, as opposed to 'intent,' to infer discrimination, and redresses disproportionate impact through 'targeted' action and resources.

Executive Order 12898

In response to growing public concern and mounting scientific evidence, President Clinton on 11 February 1994 issued Executive Order 12898, 'Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations.' The Order attempts to address environmental injustice within existing federal laws and regulations. It reinforces the Civil Rights Act of 1964, Title VI, which prohibits discriminatory practices in programs receiving federal funds. The Order also focuses the spotlight back on the 1969 National Environmental Policy Act, a law to ensure for all Americans a safe, healthful, productive, and aesthetically and culturally pleasing environment (Council on Environmental Quality, 1997).

11 February 2014 marked the twentieth anniversary of the historic Environmental Justice Executive Order 12898.

Although the Environmental Justice Executive Order was signed by President Clinton 20 years ago, it has never been fully implemented. After lying dormant for nearly a decade under the George W. Bush administration, the Environmental Justice Executive Order received some new life in 2010 under the Obama administration – with the reinvigoration of the Interagency Working Group that called for updating more than a dozen agencies' Environmental Justice strategic plans and Plan Environmental Justice 2014, a road map designed to help EPA integrate environmental justice into its programs, policies, and activities. The goals of the plan are to protect health in communities overburdened by pollution; empower communities to take action to improve their health and environment; and establish partnerships with local, state, tribal, and federal organizations to achieve healthy and sustainable communities.

Communities under Siege

A growing body of evidence reveals that people of color and low-income persons have borne greater environmental and health risks than the society at large in their neighborhoods, workplace, and playgrounds (Bryant, 1995; Bullard, 1999a,b,c, 2000; Stretesky and Hogan, 1998; Bullard and Wright, 2009; Bullard et al., 2011; Bullard and Wright, 2012; Adeola, 2012; Westra, 2013). An Institute of Medicine (1999) concluded that government, public health officials, and the medical and scientific communities need to place a higher value on the problems and concerns of environmental justice communities. The IOM study confirmed what most impacted communities have known for decades. People of color and low-income communities are (1) exposed to higher levels of pollution than the rest of the nation, and (2) experience certain diseases in greater numbers than the more affluent, white communities (Institute of Medicine, 1999).

The 2002 *Air of Injustice* study found dirty power plants are not randomly distributed across the US landscape. More than 78% of all African-Americans live within 30 miles of a power plant, the distance within which the maximum effects of the smokestack plumes are expected to occur. This is compared to 56% of whites and 39% of Hispanics (Black Leadership Forum et al., 2002).

In 2007, the *Toxic Wastes and Race at Twenty* study found people of color make up the majority (56%) of those living in neighborhoods within two miles of the nation's 413 commercial hazardous waste facilities (Bullard et al., 2007). People of color make up a much larger (over two-thirds) majority (69%) in neighborhoods with clustered facilities, and people of color in 2007 were more concentrated in areas with commercial hazardous sites than in 1987. Additionally, research on polluting facilities concluded that two-thirds of those living within a mile of such facilities are people of color, while two-thirds of those living more than 2½ miles away are white (Pastor et al., 2007).

Downey and Hawkins (2008) conducted a study on race, income, and environmental inequality in the United States in which they concluded African-Americans experience such a high air-pollution burden that black households with incomes of $50 000–$60 000 live in neighborhoods that are, on average, more polluted than neighborhoods of white households with incomes less than $10 000.

In tracking pollution from individual companies to specific communities, the corporate environmental justice performance scorecard shows the most polluted places tend to have significantly higher-than-average percentages of people of color (Ash et al., 2009). In examining the top 10 companies on the 'Toxic 100' list, people of color bear more than half of the human health impacts from the toxic air released by these industries.

Students of color are more likely to attend schools in heavily polluted areas than their white counterparts. While 44.4% of all white students in states attend schools located in the top 10% of the most polluted locations in the state, 81.5% of all African-American children and 62.1% of all Hispanic students attend schools in the most polluted zones (Mohai et al., 2011).

Unequal Protection

The *National Law Journal* uncovered glaring inequities in the way the federal EPA enforces its giant Superfund laws. White communities see faster action, better results, and stiffer penalties than communities where blacks, Hispanics, and other people of color live (Lavelle and Coyle, 1992). Clearly, communities that are located on the 'wrong side of the tracks' are at special risk from exposure to environmental hazards. Race has been found to be independent of class in the distribution of air pollution, contaminated fish consumption, location of municipal landfills and incinerators, abandoned toxic waste dumps, polluting industries, and lead poisoning in children (Commission for Racial Justice, 1987; Agency for Toxic Substances and Disease Registry, 1988; Pirkle et al., 1994).

Far too many people of color communities have become environmental 'sacrifice zones' where polluting industries expose residents who live on the fence line to dangerous emissions and releases into the air, water, and ground. African-Americans are 79% more likely than whites to live in neighborhoods where industrial pollution is suspected of posing the greatest health danger. In Houston, the nation's fourth largest

city, Hispanic and black residents who live near the polluting industrial facilities that line the Houston Ship Channel and near its booming Port pay the ultimate price with their health. As Houston expands its port, residents near the Houston Ship Channel fear the worst. Even before the Houston Port expansion, the mostly Hispanic and black East Houston neighborhoods bordering the port are already exposed to some of the worst air pollution in the country. A 2013 survey, conducted by the Healthy Port Communities Coalition, found that residents of five neighborhoods bordering the Houston Ship Channel suffer from higher rates of cancer and respiratory illnesses in the state.

Many poor and people of color communities are on the frontline of industrial accidents. And because of their close proximity to industrial corridors and transportation routes, they are exposed to elevated health risks from accidents, leaks, spills, explosions, and derailments. In 2004, more than half of the nation's 60 000 pressurized rail tank cars did not meet industry standards, and they raised questions about the safety of the rest of the fleet as well. Every day, deadly 'time bombs' haul their toxic loads through populated areas exposing millions of Americans to potential threats, both accidental and deliberate. Residents who live on the 'wrong side of the tracks' know their neighborhoods are prime locations for accidents waiting to happen.

The Harry Holt family wells and drinking water in Dickson, Tennessee, were poisoned with trichloroethylene (TCE) from a county-owned landfill. A battery of government tests were performed on duck ponds and wells where dogs were waiting to be euthanized. However, a black family's well that lies just 54 feet from the leaky Dickson County Landfill was not tested for 9 years, 1992 through 2001. It appears that government officials cared more about ducks and dogs than protecting the health and safety of law-abiding black homeowners and taxpayers. In 2003, the family sued the City and County of Dickson, the State of Tennessee and the company that dumped the TCE.

After more than 8 years of litigation, on 7 December 2011, a $5.6 million settlement agreement was finally worked out with the Dickson City and County governments on the NRDC and Holts' suit and a $1.74 million settlement to be paid to 11 Holt family members on the family's National Association for the Advancement of Colored People (NAACP) civil rights suit with monies from an October settlement reached with three companies that were defendants in the Holts' NRDC case. Harry Holt died of cancer in January 2007. His daughter, Sheila Holt Orsted is recovering from breast cancer. The county spent more than $3 million and the city almost $1.9 million on the lawsuits fighting the black family.

Even when the government has the facts about contamination and health impacts, there is no guarantee that it will act. For example, a federal survey 1999 and repeated in 2006 by the US ATSDR found dioxins in the Mossville, Louisiana, residents to be two to three times the average. Researchers have also discovered dangerous levels in residents' homes and on yards where children of Mossville play. Mossville is an unincorporated community, founded by African-Americans in the 1800s on the outskirts of Lake Charles, Louisiana, home to four vinyl production facilities. Vinyl chloride was documented to be present in the local air at levels 120 times higher than the ambient air standard. The pollution has become so unbearable that many residents have called for a community buyout and relocation. In July 2013, Sasol Lt., a South African energy giant, offered to voluntary buyout of homes in the Mossville area. The company plans a $14.5 billion complex near the community to turn natural gas into chemicals and fuels.

Childhood Lead Poisoning

Lead poisoning is the number one environmental health threat to children of color in the United States. Figures reported in the July 1994 *Journal of the American Medical Association* on the Third National Health and Nutrition Examination Survey (NHANES III) revealed that 1.7 million children (8.9% of children aged 1–5) are lead poisoned, defined as blood lead levels equal to or above 10 μg deciliter. The NHANES III data found African-American children to be lead poisoned at more than twice the rate of white children at every income level (Pirkle et al., 1994). Over 28.4% of all low-income African-American children were lead poisoned, compared to 9.8% of low-income white children. During 1976–91, the decrease in blood lead levels for African-American and Mexican-American children lagged far behind that of white children.

In California, a coalition of environmental, social justice, and civil libertarian groups joined forces to challenge the way the state carried out its lead screening of poor children. The Natural Resources Defense Council, the NACCP Legal Defense and Education Fund (LDF), the American Civil Liberties Union, and the Legal Aid Society of Alameda County, California won an out-of-court settlement worth $15 million–$20 million for a blood lead-testing program. The lawsuit, *Matthews vs Coye*, involved the failure of the state of California to conduct federally mandated testing for lead of some 557 000 poor children who receive Medicaid. This historic agreement triggered similar lawsuits in several other states that failed to live up to the federal mandates.

The Centers for Disease Control (2013) reported that about 535 000 children aged between 1 and 5 years in the United States are at risk for lead poisoning or about 1 in 38 children. The CDC reduced threshold for lead poisoning from 10 μg to 5 μg and found that between 1999 and 2010 2.6% of those children showed levels above the new threshold. And as was found in all previous reports, poor children, those living in dilapidated older houses, and African-American children are at higher risk for lead poisoning.

The Path of Least Resistance

The southern United States has become a 'sacrifice zone' for the rest of the nation's toxic waste. Toxic waste follows the path of least resistance. And in many instances, this translates into poor and people of color communities. In December 2008, a wall holding back 80 acres of sludge from the Tennessee Valley Authority (TVA), Kingston Fossil Plant broke spilling more than 500 million gallons of toxic coal ash over a dozen homes and up to 400 acres of the surrounding landscape, endangering aquatic life and the water supply for more than 25 000 residents. Six months after this tragedy in July 2009, a major

environmental injustice was perpetrated by EPA Region 4 approval of TVA's decision to ship 5.4 million cubic yards of toxic coal ash by railcar from the mostly white east Tennessee Roane County to a landfill located in the heart of the Alabama Black Belt, Perry County (69% African-American with more than 32% of its residents living in poverty) and to rural Taylor County, Georgia (41% of the population is African-American and more than 24% of residents live in poverty). TVA's toxic waste disposal decision is consistent with the theme of *Dumping in Dixie: Race, Class, and Environmental Quality* (Bullard, 2000), which illustrates that all communities are still not created equal. Shipping toxic waste to poor and people of color communities is also not news since an overwhelming share of waste facilities are located there.

Lax enforcement of environmental regulations has left the region's air, water, and land the most industry-befouled in the United States. Louisiana typifies this pattern. Nearly three-fourths of Louisiana's population, more than 3 million people, get their drinking water from underground aquifers. Dozens of aquifers are threatened by contamination from polluting industries. The Lower Mississippi River Industrial Corridor has over 125 companies that manufacture a range of products including fertilizers, gasoline, paints, and plastics. Environmentalists and local residents have dubbed this corridor as 'Cancer Alley' (Motavalli, 1998; Bullard, 2000).

Norco is located in St. Charles Parish, approximately 40 miles northwest of New Orleans. The town's name of Norco is derived from the New Orleans Refinery Company. The Old Diamond Community is more than 100 years old. As a result of Shell's Industrial expansion, the size of the Old Diamond Community has been shrinking.

The mostly African-American Old Diamond community in Norco is sandwiched between the Motiva and Shell refineries. The community is more than 100 years old and many of the residents can trace their ancestry to former slaves who purchased land from their former plantation owners. Pollution from the refineries has been a constant pain for the nearby residents who have been fighting for a buyout and relocation from the pollution. In 2002, after a decade of struggle, Concerned Citizens of Norco achieved an environmental justice victory. Shell agreed to a community buyout. And for her crusading environmental justice work, community leader Margie Richard, a lifelong Old Diamond community resident, won the Goldman Prize in 2004.

Corporate Welfare

Louisiana is also a leader in doling out corporate welfare to polluters. Industries routinely pollute the air, ground, and drinking water while being subsidized by tax breaks from the state. In the 1990s, the state wiped off the books $3.1 billion in property taxes to polluting companies. The state's top five worse polluters received $111 million dollars over the past decade (Barlett and Steele, 1998).

Subsidizing polluters is not only bad business, but it does not make environmental sense. A growing body of evidence reveals that "states with lower pollution levels and better environmental policies generally have more jobs, better socioeconomic conditions and are more attractive to new businesses" (Templet, 1995). Louisiana and other states could actually improve their general welfare by enacting and enforcing regulations to protect the environment.

In July 2013, the Southeast Louisiana Flood Protection Authority-East filed a lawsuit against dozens of energy giants asking the courts to force them to pay for decades of damage to fragile Louisiana coastal wetlands that help buffer the effects of hurricanes on the region (Schwartz, 2013). The lawsuit argues that energy companies such as BP and Exxon Mobil should be held responsible for fixing environmental damage they have caused to Louisiana wetlands – killing vegetation, eroding soil, and allowing salt water into freshwater areas. Louisiana Governor Jindal opposed the lawsuit.

Dumping on Native Americans

It should not be a surprise to anyone to discover that Native Americans have to contend with some of the worst pollution in the United States (Tomsho, 1990; Taliman, 1992). Native American nations are prime targets for waste trading. More than three dozen Indian reservations were targeted for landfills, incinerators, and other waste facilities in the early 1990s. Native American groups and their allies defeated most of these waste proposals.

Racism operates in energy production (mining of uranium) and disposal of wastes on Indian lands (Churchill and LaDuke, 1983). The practice has left many sovereign Indian nations without an economic infrastructure to address poverty, unemployment, inadequate education, and health care, and a host of other social problems. In 1999, residents on the Eastern Navajo Reservation in Church Rock and Crown Point, New Mexico formed Eastern Navajo Dine Against Uranium Mining (ENDAUM) and the New Mexico Environmental Law Center filed suit with the Nuclear Regulatory Commission to block a permit for uranium mining in Church Rock and Crown Point, New Mexico. ENDAUM has kept the fight going for over 16 years and Hydro Resources has yet to break ground. In December 2013, US Bankruptcy Judge Allan L. Gropper ruled that Anadarko and Kerr-McGee companies are liable for the contamination mess they have created on the Navajo Nation and set damages ranging between $5.1 and $14.1 billion (ICTMN Staff, 2013). And because of the abandoned uranium mines, tailings and contaminated waste sites that dot the reservation, many families have to travel 15–20 miles for water to drink, cook, bath in, and water their animals because their wells have been contaminated by uranium mining.

Transboundary Waste Trade

Hazardous waste generation and international movement of hazardous waste pose some important health, environmental, legal, and ethical dilemmas. Shipping hazardous wastes from rich communities to poor communities is a global problem. In the real world, all people, communities, and nations are not created equal. Unequal interests and power arrangements have allowed poisons of the rich to be offered as short-term remedies for poverty of the poor. This scenario plays out domestically (as in the United States where low income and people of color communities are disproportionately impacted by waste facilities and 'dirty' industries) and internationally – where

hazardous wastes move from OECD states to non-OECD states (Khoo and Rau, 2009).

The conditions surrounding the more than 2000 maquiladoras, assembly plants operated by American, Japanese, and other foreign countries, located along the 2000-mile US–Mexico border may further exacerbate the waste trade. The industrial plants use cheap Mexican labor to assemble imported components and raw material and then ship finished products back to the United States. Nearly a half million Mexican workers are employed in the maquiladoras.

All along the Lower Rio Grande River Valley maquiladoras dump their toxic wastes into the river, from which 95% of the region's residents get their drinking water (Hernandez, 1993). In the border cities of Brownsville, Texas and Matamoras, Mexico, the rate of anencephaly – babies born without brains – is four times the national average. Affected families have filed lawsuits against 88 of the area's 100 maquiladoras for exposing the community to xylene, a cleaning solvent that can cause brain hemorrhages, and lung and kidney damage.

The Mexican environmental regulatory agency is understaffed and not equipped adequately to address the problem (Barry and Simms, 1994), a situation that has not changed since.

As the United States tightens regulations on lead emissions, battery recycling operations have moved to Mexico. After 2008, new US limits on lead pollution have made domestic recycling costly. Lead emission standards in Mexico are one-tenth as stringent as US standards. The United States does not treat international battery shipments as hazardous waste as is common among developed nations. Between 2004 and 2011, the US exports of dead batteries to Mexico increased by anywhere from 449% to 525% (Secretariat of the Commission for Environmental Cooperation, 2012). In 2011, the dead batteries headed to Mexico would have filled 17 952 tractor-trailers. Mexico is rapidly becoming a 'pollution haven.'

Conclusion

The environmental justice movement emerged in response to environmental and social inequities, threats to public health, unequal protection, differential enforcement, and disparate treatment received by the poor and people of color. The movement redefined environmental protection as a basic right. It also emphasized pollution prevention, waste minimization, and cleaner production techniques as strategies to achieve environmental justice for all Americans without regard to race, color, national origin, or income.

The poisoning of African-Americans in Louisiana's 'Cancer Alley,' Native Americans on reservations, and Mexicans in the border towns all have their roots in a system characterized by economic exploitation, racial oppression, and devaluation of human life and the natural environment. Unequal political power arrangements have allowed poisons of the rich to be offered as short-term economic remedies for poverty and unemployment. Having industrial facilities in one's community does not automatically translate into jobs for nearby residents. Similarly, tax breaks and corporate welfare programs have produced few new jobs by polluting firms.

The environmental justice movement has established clear goals of eliminating unequal protection. This call for environmental and economic justice does not stop at the US borders but extends to communities and nations that are threatened by the export of hazardous wastes, toxic products, and 'dirty' industries. Environmental justice leaders are demanding that no community or nation, rich or poor, urban or suburban, black or white, should be allowed to become a 'sacrifice zone' or dumping grounds. They are also pressing governments to live up to their mandate of protecting public health and the environment.

Environmental Movements

Abstract

Originating in nineteenth century concerns with the protection of unspoiled landscapes and natural resource conservation in the United Kingdom and the United States, environmentalism is now a global phenomenon, embracing a number of different perspectives. The development of different and multiple environmental movements worldwide is the outcome of contingent historical processes and events, the development of specific discourses, and the mobilization of material and cultural resources. There is no one 'environmental' movement. Rather, there are a number of different environmental movements that focus on a wide range of issues.

Introduction

Over the past century, concern over environmental degradation has manifested itself in various organized efforts across the globe. Environmental movements are networks of actors who advocate for a range of environmental concerns. There is not just one environmental movement (Doyle and MacGregor, 2014: 1). Rather, there are a number of partially overlapping networks that interact at local, regional, national, and international levels. These movements involve groups and organizations that range in size from small informal local groups that have no organizational affiliation, to large formalized international organizations, and even political parties, especially Green parties. The aims and orientations of these different groups vary widely, with diverse groups advocating the adoption of technological measures, various types of international accords, economic measures, or the wholesale transformation of capitalism. They also vary regarding the level of government policy they aim to influence, from local authorities and municipalities to national and international institutions, as well as specific corporate actors (Dietz and Garrelts, 2014).

Environmental movements are engaged in collective action motivated by their participants' shared identity or concern about environmental issues but they are not, however, identical with organizations or episodes of protest. It is only when organizations (and other, usually less formally organized actors) are networked and engaged in collective action, whether or not it involves protest, that an environmental movement exists (see Diani, 1995: 5; Rootes, 2004). Such linkages are not always readily visible. Where environmental movements are well established, they may focus on less visible forms of action such as lobbying and constructive engagement with governments and corporations rather than highly visible protest. Where environmentalism has become entrenched, there are many less publicly visible linkages among groups and organizations, and the full range of movement activities is less likely to be adequately reported in mass media. This has implications for scholars researching movements, with no single research strategy likely to yield a complete picture. Organizational studies neglect the less organized parts of the movement, and whilst studies of protest events (Rootes, 2003) may represent the most visible face of the movement, they cannot adequately portray less public – or simply less publicized – movement activities, including those that happen locally and out of sight of national mass media.

The Rise of Environmental Movements

The development of the different and multiple environmental movements across the globe is the outcome of contingent historical processes and events, the development of specific discourses, and the mobilization of material and cultural resources that results in a definable network of interaction. Over the past century, environmental movements have grown in range from a few isolated nature preservation groups in the United States, the United Kingdom, Germany, and other European countries into a worldwide phenomenon that encompasses an enormous range of issues. As industrialization and the exploitation of natural resources accelerated, their impacts on the environment became increasingly obvious and this motivated individuals to raise alarms about the consequences. In the 1960s, in a context of increasing aspirations of citizens to public participation, writers such as Rachel Carson cogently framed the issues of human actions that caused environmental degradation and thereby inspired individuals to join together in collective actions (Carson, 1962). These new cultural resources formed an important component in the development of environmentalism (Carmichael et al., 2012; Brulle and Benford, 2012). Motivated by these new perspectives and aided in the United States by foundation support, environmental movements rapidly expanded, starting in the 1960s in the United States and western Europe, and then spreading across the globe in subsequent decades. This, joined with the radical critique of capitalist industrialism and representative democracy associated with the New Left and various countercultural trends, created the public space for the development of new social movements, as well as furnishing their tactical repertoire. More radical environmental movement organizations (EMOs) that embraced nonviolent direct action arose and spread from the United States to western Europe. Friends of the Earth (FoE) and Greenpeace (Zelko, 2013) were started by environmentalists dismayed by the apparent timidity of more traditional environmental organizations such as the Sierra Club,

and in response to the demands of a new, self-confident, and participatory generation to participate directly in activism. The internationalism of the new EMOs and their skillful exploitation of mass media to excite public concern in order to put pressure on governments and corporate decision-makers were in tune with the times, and these were the fastest growing EMOs during the 1980s.

On both sides of the Atlantic, the history of environmentalism has been one of successive waves of critique, innovation, and incorporation. The rise of the new EMOs encouraged innovation in the agendas and tactics of older conservation organizations, and by the end of the 1980s networking among older and newer organizations and joint campaigns were increasingly common. By then, however, dissatisfaction with institutionalized reform environmentalism was stimulating the rise of groupings of radical ecologists and the environmental justice movement (EJM). Beginning in the 1970s in the United States and in parts of the global South, movements developed that were focused on environmental justice and the unequal environmental burden suffered by poor and disenfranchised peoples.

Many organizations formed in earlier waves of environmental concern have adapted to accommodate subsequent concerns and developments in ecological consciousness. In the United States, despite observers' doubts that established, 'wilderness obsessed' EMOs are capable of accommodating the concerns of the EJM, especially after 2000, the Sierra Club and Greenpeace took up aspects of the environmental justice agenda. In western Europe, the environmental justice frame has been increasingly adopted, especially by FoE, while established EMOs such as the World Wide Fund for Nature (WWF) and the national bird protection societies have developed more inclusive ecological perspectives and broadened the range of their campaigns to include issues of habitat and the welfare of human populations (Rootes, 2006). Despite noteworthy differences in perspectives, areas of concern, priorities, and tactics from one group or organization to another, there are network links of varying kinds and degrees of strength and intensity. It is the persistence of these that demonstrates the vitality of environmental movements (Rootes, 2004).

Values and Social Bases of Environmentalism

The rise of values and attitudes favorable to environmentalism is frequently explained in terms of 'post-materialism' (Inglehart, 1977). According to this thesis, post-material values prioritizing aesthetic, intellectual, and self-actualization needs are gradually displacing materialist values that place higher priority on economic and security needs, chiefly because younger generations raised in relative affluence and security are steadily replacing older generations who, during their formative years, more often experienced economic privation and the insecurities of war. The rise of environmentalism was counted among the consequences of this 'culture shift.'

Yet Dalton and Rohrschneider (2002) examined the link between individual endorsement of post-materialist values and membership in environmental organizations and found that the correlation was modest in wealthy nations and barely existed in poor ones. Post-materialism may not be as good a predictor of environmentalism as some observers assume because environmentalism combines a post-materialist aesthetic and principled concerns with environmental protection with essentially materialist concerns with safety and security, whether about air or water pollution, or the impacts of nuclear energy and climate change. Even global environmental concern, often considered to be a post-materialist gesture of concern by citizens of the rich North for the plight of the poor of the global South, might be portrayed as materialist since the effects of environmental degradation in the South will sooner or later be felt even in the North.

Post-materialism is also relatively weakly correlated with support for environmentalism because concerns for the environment are held both by different social groups: on the one hand, highly educated 'post-materialist' ecologists, who are more concerned about global environmental problems with relatively remote effects than they are fearful for their own security; and, on the other hand, by people, usually less well educated, who are more worried about the threats that environmental damage poses to their own material security. Post-materialism is a better predictor of environmental activism than of environmental concern because environmental activism, like most forms of political activism and unlike concern, is highly correlated with higher education. Similarly, the significant correlation that Dalton (2005) found between national affluence and membership in environmental organizations might exist simply because affluence is associated with membership in civic groups more generally.

Most research on the social backgrounds of environmental activists and members of national EMOs has concluded that they are relatively highly educated, more likely to be employed in teaching, creative, or caring professions, and very often the offspring of highly educated parents (Rootes, 1995). For this reason, environmentalism has sometimes been interpreted as the self-interested politics of a 'new class' comprised of people who are occupationally engaged with culture and the manipulation of symbols, and who are opposed or indifferent to the interests of those whose labor involves the manipulation of material things. However, environmental activists are not exclusively drawn from such backgrounds, and approval of EMOs and environmental activism, as well as pro-environment attitudes, is more widespread in most societies than the 'new class' thesis would suggest.

Grassroots environmental movements involve a broader cross section of society than major national EMOs. This is partly because less socially and economically privileged communities are more likely than the rich and the resourceful to be subjected to unwanted and environmentally damaging developments, but also because it is also easier to enter local political arenas than to participate effectively in national politics. Women play more prominent roles in grassroots mobilizations than in national EMOs, both because women are in general more involved in local communities, and also because they are more likely to be confident of acting in the local community than in the wider public sphere. Grassroots environmental activism is thus an important element of the mobilization of environmental movements: it makes the movement more broadly socially representative than it might otherwise be, and may also provide opportunities for social learning about environmental issues, acting as a school for

participation generally, an entry point for new activists and new issues, and even a source for the revitalization of national environmental organizations.

Culture and Forms of Action

Environmental movements across the globe involve a wide-ranging and complex network of interaction among a number of different organizations. They are composed of people and groups with many different viewpoints, which define their perception of the natural environment and their subsequent issue focus. Perspectives and priorities differ between and among environmentalists in the global North and the global South, as is apparent in the regional differences among the 74 national affiliates of FoE International (Doherty and Doyle, 2013). To understand such complex sets of interactions, sociologists have developed discursive frame analysis to capture and interpret different worldviews or 'discursive frames' within a social movement (Benford and Snow, 2000; Benford, 2011). A discursive frame is the set of cultural viewpoints that informs the practices of a community of social movement organizations, defines the goals and purposes of the organization, and provides guidance for action. In turn, this frame influences the organization's tactics, and methods of resource mobilization (Benford and Hunt, 1992; Brulle, 2000). It also defines a network of interaction among other similar organizations. The character of this network defines the scope and strength of the movement organization, relationships with other movement organizations and other institutions.

Within any social movement, there are generally multiple frames, which define distinct movement sectors or 'wings' that diverge in their definitions of problems, strategies, and methods of organization (Snow, 2004). This is certainly the case among the environmental movements. Theorists have identified a number of environmental networks based on their particular discursive frames, but these are highly contextual definitions that are applicable only within certain cultural and political boundaries. Organizational formalizations of ideological division are more likely in the formal party-political arena, where membership tends to be exclusive, than in movements, where organizations are more fluid, overlapping memberships are common, and the flexibility of the network structure may accommodate differences without much overt conflict. Moreover, common ground among organizations may mask greater diversity among the perspectives of rank-and-file activists (Wahlström et al., 2013).

Although the discursive frames adopted by environmentalists have consequences for the ways in which they campaign and the forms of organization they adopt (Brulle, 2000) but, as Dalton (1994) discovered, whether European EMOs had originally been committed to conservationism or ecologism made surprisingly little difference to their choices of strategies, tactics, and styles of action. The apparent convergence within the broad environmental movement sector was not simply a matter of the progressive institutionalization and incorporation of more radical organizations. FoE and Greenpeace may have started as activist groups and learned how to behave in ways that opened channels of communication to governments and/or powerful corporate actors, but some traditional conservationist organizations have become less conflict averse and more skilled in the use of mass media. EMOs' values do influence their strategy and tactics, but even more influential is the pattern of opportunities and constraints that derives from the structures of the national political systems within which those organizations operate (Dryzek et al., 2003).

Even where they embrace direct action, environmental movements almost always restrict themselves to nonviolent forms of action, but movement subcultures are not isolated from wider social and political contexts. Thus, violent environmental protests in Italy and Spain in the 1980s were part of the spillover from more general political conflicts – the political violence of the 1970s in Italy and militant Basque nationalism in Spain. Similarly, the wave of confrontational environmental protest in Britain in the 1990s was shaped by widespread and occasionally riotous protest against the Thatcher government's poll tax (Rootes, 2003). In general, however, national political cultures explain less of the variation in environmental activists' tactics than do political conjunctures.

The great majority of environmental organizations are either engaged in practical conservation work or focus upon informational and educational strategies or lobbying. Even for Greenpeace, the archetypical professionalized protest organization, protest is only a small part of its work. The small minority of groups that rely on protest are distinguished by the discourses they articulate. Those that employ the discursive frames of deep ecology and environmental justice are disproportionately responsible for the relatively small number of highly publicized environmental protests, especially in the United States. (Brulle, 2000: 246; Carmin and Balser, 2002).

Institutionalization

The numbers of members and supporters of preservation and conservation organizations and EMOs have grown since the 1970s. As a result, many of those organizations have become substantial operations with annual budgets in the millions, and employees numbering hundreds or thousands. As a result, they have increasingly become formal organizations, internally bureaucratized, and employing salaried professional employees rather than the enthusiasm of volunteers. Although some democratic organizations exist in the environmental movement, most lack formal participatory mechanisms and are effectively oligarchies governed by self-selecting boards (Brulle, 2000). These 'professional social movement' organizations (Zald and McCarthy, 1987) have been labeled 'astro turf' organizations (Cigler and Loomis, 1995) or 'protest businesses' (Jordan and Maloney, 1997), in which professional staff dominate and 'members' are merely financial supporters. Some, like Greenpeace, are unabashed about this; others preserve a semblance of democracy in principle but are in practice no less oligarchical (Rootes, 2009).

It used to be assumed that 'success' for a social movement meant its institutionalization, usually as a political party. Yet although Green parties emerged from the 1970s onward, and began by the 1980s to win seats in some European legislatures, they were more often products of antinuclear campaigns than direct representatives of environmental movements, and they are

not institutionalized vehicles of the environmental movement in the way that socialist parties were of the labor movement. Green parties have prospered, especially in northern Europe and Australasia, but their relations with environmental movements have been problematic, especially where Green parties have entered government, as they have in countries as diverse as Germany, Italy, France, Finland, the Czech Republic, and Ireland.

Where conditions have favored the development of institutionalized EMOs, they have become formal organizations embedded in networks of policy advocacy and implementation, and so have constituted a 'public interest lobby' (Diani and Donati, 1999) or an 'advocacy community' (Bosso, 2005). To protect their reputations in the eyes of more powerful actors in government and corporations, environmental organizations that have secured access on the basis of their expertise and politically nonpartisan status have generally been careful to keep some distance between themselves and others, such as Green parties, who have attempted to enter the political arena directly, and especially where Green parties have been only marginal players in formal politics.

In the United States, where political structures have discouraged the development of Green parties, charitable foundations have been a substantial source of funding for most major EMOs. However, most foundation funding goes to moderate organizations that use the traditional discourses of conservation, preservation, and liberal environmentalism. Concentrated on a relatively small number of large EMOs involved in political advocacy work (Brulle and Jenkins, 2005), charitable funding has steered the major environmental organizations into neoliberal environmental protection strategies that have become disconnected from the everyday concerns of their constituencies (Brulle, 2014). In Britain, foundation funding is less significant, but strongly favors organizations engaged in practical environmental protection and remediation rather than advocacy (Rootes, 2009).

Some claim that the institutionalization of EMOs, and their dependence upon foundation funding, has robbed them of the capacity and, even the will, to mobilize large numbers of people in collective action, thus depriving them of the 'veto power' – the ability to disrupt 'business as usual' – that social movement scholars have usually considered to be the ultimate basis of the power of social movements (van der Heijden, 1997). Interestingly, however, those organizations that claim to speak for grassroots environmental activists appear to be scarcely less oligarchic than others: most organizations associated with the EJM in the United States lack mechanisms of democratic accountability (Brulle and Essoka, 2005).

Elsewhere, the institutionalization of EMOs has not simply entailed the deradicalization of movements or a loss of shared identity. In Germany, a substantially institutionalized movement coexisted in the 1990s with the revival of highly confrontational, at times violent, antinuclear protest, as established EMOs gave assistance to local antinuclear groups (Rucht and Roose, 2003). In Britain during the 1990s, EMOs grew in numbers and size as well as access and influence, but reported environmental protest increased and became more, rather than less, confrontational (Rootes, 2003). In the United States, the rise of the climate movement, centered on the organization 350.org led by Bill McKibben, injected new activism and purpose into the environmental movement.

The rise of new, more radical groupings such as Earth First! can be traced to dissatisfaction with the apparent timidity of more established EMOs. Nevertheless, despite variations in their tactical repertoires, there is a measure of shared identity among environmental campaigners. Even the radical 'disorganizations' most committed to direct action have often been connected by networks of advice and support to more established organizations. The support that established EMOs have given to direct action groups may not have been very publicly visible, but the sense of collective identity among the constituent parts of the environmental movement grew as groups came to practice a division of labor and realized the advantages of cooperation, most notably around climate change. This stimulated the rise of new forms of direct action – such as the Climate Camps in Britain – and drew members and supporters of even conservation organizations into street demonstrations (Rootes, 2012).

These experiences show that it is possible for an environmental movement to retain many of the characteristics of an emergent movement whilst taking advantage of the opportunities presented by institutionalization. Institutionalization has not been a barrier to the mobilization of protest. Whilst some writers have referred to the 'self-limiting radicalism' of Green parties, it is the 'self-limiting institutionalization' of environmental movements that is more striking and that has more profound implications.

The survival of environmental movements and their resistance to the deradicalizing effects of institutionalization has distinguished them from the other 'new social movements,' perhaps because pressing environmental problems are a chronic condition of an industrialized world. Northern environmental movements are not universally anticapitalist but they have often, as in as campaigns against genetically modified organisms and neoliberal globalization, been influenced by the critical analyses of radically anticapitalist groups.

In the global South, because environmental campaigns are usually bound up with campaigns for human, democratic, and economic rights, they often do not take the form of specifically environmental movements, but they do campaign for global environmental justice and struggle against extractive industries, transboundary pollution and waste flows, free trade agreements, and the ideological and social systems that reinforce such practices, including militarization, racism, capitalism, patriarchy, and other social hierarchies. In other words, the global EJM merges concerns with ecological sustainability with a demand for social justice and human rights.

These movements view the global political economy as shifting risks and hazards from North to South, from rich nations to poor communities between and within nations, and from racially privileged elites to racially despised communities. Often radical in their approach, they challenge the sources of power in the global political economy – governments, transnational corporations, international financial institutions, and racist and classist ideologies – and seek to destabilize, disrupt, and open them up in the hope of creating a more just transnational political space.

In postcommunist central and eastern Europe and in east Asia, environmental movements often provided cover for prodemocracy activists (Lee and So, 1999). In sub-Saharan Africa, where states are weaker and affluent civil societies are scarcely

developed, environmental movements have been less vigorous (Mittelman, 1998) and, as in recently democratized central and eastern Europe, environmentalists' successes have often depended upon support from Northern/Western EMOs and human rights organizations. Dependence on foreign assistance may, however, displace local agendas and divert activists from efforts to mobilize local people. Perhaps for this reason, in challenging authoritarian states, environmental movements have had greatest impact where they mobilized local people and incorporated local cultural values and rituals, empowering local activists (Lee and So, 1999: 291).

Impacts

The direct impacts of social movements are always hard to distinguish from the effects of social and political changes external to the movement. The rise of environmental movements from the late 1960s coincided with the development of legislation and state agencies designed to protect the environment but, rather than the one leading to the other, both were products of developing environmental awareness amongst a larger public.

Environmental activists played major roles in preserving Californian redwood and Tasmanian forests and the Australian Great Barrier Reef, and Greenpeace's campaign against the dumping of waste at sea changed the policies of oil companies and perceptions of the sea as a limitless waste repository. Grassroots mobilization over issues of toxic pollution has forced states to take actions to remediate existing sites, and to institute preventive measures to forestall future incidents. Environmental movements have stimulated and mediated the concerns of the wider public, and reflected and amplified concerns that originated in scientific and policy communities. Sometimes they have succeeded in sensitizing mass publics and decision-makers to environmental issues that might not otherwise have been so salient.

However, one glaring failure of environmentalism has been their inability to mobilize meaningful action on climate change. After the failure of COP15 in 2009, much of the movement refocused on national and regional efforts. While this has produced some marginal results, it has yet to have any substantial impact upon the practices that contribute to the increasing urgency of the climate change issue, especially as, in deference to powerful economic interests, countries such as Canada and Australia retreat from previous commitments and developing countries continue to increase their greenhouse gas emissions. EMOs may have set the agenda of environmental reform and succeeded in framing the issues as matters of global collective responsibility but, as environmental issues have moved up political agendas, EMOs have struggled to meet expectations. Unable to participate effectively in high politics, they may be drawn back to the grassroots, but it is not clear whether this will produce a wider mobilization and more effective action on climate change.

Despite frequent references to 'the' environmental movement, and even to 'the global environmental movement,' there is so much variation among and within local and national environmental movements that a global environmental movement remains an aspiration rather than an accomplished fact. Obstacles to a global movement include the wide diversity of material conditions, cultures, languages, and political circumstances. National environmental movements have flourished under conditions of stable democracy in strong states, and the absence of a developed democratic global polity is a major obstacle to the development of a *global* environmental movement. However, if the globalization of industrial capitalism increases the scale of the assault on what remains of the pristine natural environment, the gradual extension of democratic politics encourages some hope that people may yet mobilize to limit environmental degradation.

Environmental movements are not monolithic structures but are composed of a variety of discursive communities, each of which has its own specific issue focus. Despite their diversity and temporary setbacks, environmental movements are likely to continue to be major players in politics across the globe.

Environmental Planning

John C Keene, University of Pennsylvania, Philadelphia, PA, USA

© 2015 Elsevier Ltd. All rights reserved.

Abstract

With the remarkable growth in the commitment to making the activities and programs of governmental, corporate, and nongovernmental organizations more 'sustainable,' there has been a corresponding expansion in environmental planning at all levels and in all segments of society. In fact, environmental planning and management of the impacts of these different organizations' activities on the natural environment constitute key components of any comprehensive strategy for sustainable development. Governments, corporations, and nongovernmental organizations such as universities have begun to reshape programs in all of the following policy areas so as to increase their contribution to greater global sustainability: managing urban growth, land development and building construction, use and management of water, increased energy efficiency in building use and operation, increased transportation efficiency in both mass transit and automobile usage, management and reduction of environmental pollution, taking into account environmental and social impacts as well as financial profitability in managing corporate policies, more efficient production and distribution of goods and services, and better management of solid waste recycling and disposal. Many organizations have voluntarily developed policies to make their operations climate neutral within 40 or 50 years.

Introduction

For millennia, humans have realized the importance of conserving important natural resources and minimizing the damage that their activities cause to the natural environment in which they live. They have followed broad strategies to protect environmental resources and to reduce or eliminate these impacts. They sought to shape land use patterns so as to protect people from natural hazards such as floods, to prevent inappropriate consumption of natural resources, and to control emissions or discharges directly. Environmental planning embraces those activities of government agencies and private organizations whose primary purpose is to manage the impacts of the human use on the natural environment, by taking thought for the future and choosing courses of action that promote appropriate goals.

In the first decade of the twenty-first century, a paradigm shift has occurred as the concepts of sustainable development have burrowed their way into more traditional ways of viewing man's impact on the natural environment. This shift has been fitful, with false starts and stops and uneven recognition and acceptance in various segments of society. It has been comprehensive because, often first motivated by concerns over such matters as global warming, loss of biodiversity, destruction of the stratospheric ozone layer, serious water and air pollution, depletion of major ocean species, it has come to address virtually all aspects of human behavior from energy conservation, to building construction and operation, waste disposal, transportation, production and consumption, conservation of natural resources, public health, social inclusion, and global poverty (see, e.g., The European Community's Principles for Sustainable Development, 2005).

Environmental planning has become a critically important component of the new paradigm of sustainable development. Because of the scope and complexity of the activities it addresses and of their far-reaching and variable impacts, the field of environmental planning defies easy definition. Furthermore, conceptions of the relationships between humanity and the environment change over time, so that the character, goals, methods, and indeed, the very ethical foundations of environmental planning are continuously evolving. At the present time, environmental planners carry out such varied responsibilities as the analysis of the natural environment that constitutes a component for comprehensive plans, assessment of and developing strategies for reducing the emission of greenhouse gases (GHGs) that are contributing to global warming, developing better methods of recycling, using, and disposing of liquid and solid wastes, the preparation of environmental impact statements for governmental programs, the drafting of plans for recreational areas, parks, and other types of open space, and the development of policies for the protection of prime farmland, wetlands, floodplains, and other natural resource areas as part of broader urban growth management policies and plans.

In the last decade, many universities, business corporations, cities, provinces, and nations have begun to formulate policies under the general rubric of climate action plans or sustainable development strategies. Although there is certainly no uniformity or even consensus about the nature and content of these actions, they appear to be converging on a set of policies that seek both to make the institutions, businesses, and governments more economically efficient and to promote the public interest by conserving energy, reducing the rate of climate change, and reducing the amount and type of environmental pollution that results from man's activities. The intriguing thing about many of these policies is that they have been undertaken voluntarily without any government mandate.

Furthermore, it is essential to understand that, to paraphrase the words of the National Research Council in its Report, *Toward Sustainable Agricultural Systems in the 21st Century* (*2010*), sustainable development "is a complex, dynamic and political concept that is inherently subjective in that different groups in society place different emphases on each of the its numerous goals … The pursuit of sustainability is not a matter of defining sustainable or unsustainable development, but rather, it is about assessing whether choices of the practices and systems would lead to more or less sustainable systems as

measured by society's goals. Improving sustainability will require identification of key metrics and indicators that can measure progress toward these goals, together with the monitoring and collecting of date and using adaptive management."

A Brief History of Environmental Planning

Although the term, environmental planning, is of relatively recent origin, mankind has undertaken the activities it now embraces for millennia. At least 5000 years ago, the earliest urban civilizations – the 'hydraulic' societies of Sumer, Egypt, and the Indus Valley civilization in present-day Pakistan – undertook major programs to harness natural forces. Large-scale irrigation projects provided the water needed to support the broad agricultural foundation on which the urban civilizations were built. Certainly, the Romans engaged in a substantial amount of what we would today include in environmental planning as they built extensive public works, such as the dams, reservoirs, aqueducts, and the water supply and sewerage systems that served their far-flung cities.

In historic Islamic cities from Morocco to Iran, abattoirs, tanneries, and textile dyeing operations were relegated to the outer, downstream, edges of the medina (the old city), far from the Grand Mosque, the central souk (market), and the principal residential areas. Across the Islamic world after the eighth century, gardens were associated with paradise, and many of the palaces contained elaborate gardens that gave their owners respite from the harshness of the climate. Superb examples such as the fourteenth-century Alhambra palace of the Nasrid caliph, Yusuf I, in Granada, Spain (Hoag, 1977), are creations that fall within the broad definition of environmental planning. Some represent the folly of ignorance of environmental imperatives, such as Fatehpur Sikri, Mughal Emperor Akbar's magnificent palace complex built near Agra in the second half of the sixteenth century. It was abandoned after less than 15 years of occupation because of an inadequate water supply system (Fatehpur Sikri).

In Europe, in the eleventh and twelfth centuries, after a long hiatus following the collapse of the Roman Empire in the fifth century, Italian cities adopted municipal codes that regulated both the disposal of wastes (forbidding, e.g., their discharge within the town) and the number and location of pollution-generating activities (Zupko and Laures, 1996). A growing interest in nature found expression in the Renaissance gardens of Florence, Rome, and Tivoli (McHarg, 1992). Here, in the sixteenth century, artists such as Bramante, Raphael, and Palladio imposed a simple geometry on the forms of nature. A century later, landscape gardeners such as André Le Notre developed formal Baroque gardens at Versailles and Vaux-le-Vicomte, that 'testified to the divinity of man and his supremacy over a base and subject nature' (McHarg, 1992). A strongly divergent tradition developed in England in the eighteenth century. Landscape gardeners such as Lancelot 'Capability' Brown and William Kent created the famed English landscape for their aristocratic clients, a setting for their manor houses that appeared natural but was as much an artifice of the human mind as the formal gardens of Paris and Rome (McHarg, 1992). Nature and its forms became something to be respected and idealized.

In the nineteenth century, interest in public health mounted, especially in the link between sewage discharges from rapidly growing cities, the pollution of their water supplies, and the outbreaks of typhoid and dysentery. Many major cities undertook the construction of public water supply and sewerage systems. In 1872, responding to a growing interest in the conservation of critically important natural areas, during the administration of President Grant, the United States created Yellowstone National Park, the first in what was to become an impressive system of parks. Frederick Law Olmstead designed a number of parks, the best known of which is Central Park in New York City.

The American city planning movement, which began in the early twentieth century, drew inspiration from the public health, housing, and City Beautiful movements, and from early German efforts to zone land according to its most appropriate land use. But it was concerned more with the management of new development by limiting densities and separating incompatible uses than it was with the moderation of human impacts on the natural environment and the conservation of natural areas. Environmental concerns took a backseat during World War I, the Roaring Twenties, the Depression, World War II, and the reconstruction and normalization years immediately thereafter. After World War II, Aldo Leopold articulated a new kind of ethic that called on mankind to serve as the steward of nature, not its sovereign (Leopold, 1949), and in 1962, Rachel Carson's *Silent Spring* fired the American imagination with her chronicle of the devastation that that country's profligate waste disposal, pesticide use, and weak environmental policies were wreaking on its environment (Carson, 1962). Ian McHarg argued eloquently and persuasively that plans for the development and redevelopment of rural and urban areas must be based on a comprehensive inventory of ecological data that present a complete picture of the geological, hydrological, pedological, limnological, physiographic, climatological, and biological systems in the area that is the subject of the plan (McHarg, 1969, 1992).

It was not until the 1960s and the early 1970s that a newly felt concern for the environment, and a deepening awareness of the damage that mankind was inflicting on it, resonated with something deep in people's souls. This found expression in the United States and across the world, in the enactment of a substantial body of environmental protection laws. More than in any preceding era, public and private decision makers have been called upon to take into account the environmental impacts of the various policies and infrastructural systems they propose and to develop appropriate planning strategies for dealing with them.

The recognition of the serious and growing impacts of man's activities on the environment and the development of the concept of sustainability as we now know it can be traced to the 1970s. The Club of Rome's *The Limits of Growth*, published in 1972, sounded a widely heard warning (Club of Rome, 1972). Also in 1972, the United Nations held a major conference on the Human Environment in Stockholm, and many view it to be the real font of the sustainability movement. The United Nations instituted its Environment Program in 1972, and the Cocoyoc Declaration in 1974 recognized that humanity was at a critical turning point. The Declaration stated: "Environmental degradation and the rising pressure on

resources raise the question of whether the 'outer limits' of the planet's physical integrity may not be at risk" (Friedman, 1992). Satisfying the basic needs of the world's poor was proclaimed as more important than simple growth maximization.

Most discussions of the concept of sustainability start with the definition found in the Report of the General Assembly of the United Nations' World Commission on Environment and Development (WCED) held in Stockholm in 1983. Its report, *Our Common Future* (often referred to as the Brundtland report and published in 1987) (Brundtland Report, 1987), articulated the following widely quoted definition of sustainability:

> Sustainable development is development that meets the needs of the present without compromising the ability of future generations to meet their own needs.

The Commission suggested a number of planning strategies for achieving sustainable development and recognized the importance of including social equity along with the more traditional environmental goals. It asserted that sustainability does not concern only the environment, it also must address economic inequalities and social inequities. Sustainable development rests on three pillars: protection of natural ecosystems, reduction of economic inequalities, and the creation of a more just world.

The 1992 United Nations Conference on Environment and Development (the Earth Summit) in Rio de Janeiro was a particularly important and influential international conference on environment. It adopted two major documents. The *Rio Declaration* recognized that social equity must coexist with economic development, and called on the polluting nations to contribute to cleaning up the environment. The 1992 Conference's *Agenda 21* was a lengthy document that set out a full set of goals and over 120 strategies for achieving them. Again, it recognized that "[H]humanity stands at a defining moment in its history. We are confronted with a perpetuation of disparities between and within nations, a worsening of poverty, hunger, ill health and illiteracy, and continuing deterioration of the ecosystems on which we depend for our well-being" (Sitarz, 1993). In the United States, in 1993, President Clinton created the President's Council on Sustainable Development and charged it with developing a national strategy for sustainable development in 1999, major components of which entailed environmental planning.

The 1996 Habitat II Conference in Istanbul continued that line of thinking, and confirmed that social equity and human resource development are essential components of a truly sustainable development process and a just world. Some 31 countries signed the Kyoto Protocol in December 1997, committing themselves to protecting the environment by bringing about a reduction in the emissions of GHGs, such as carbon dioxide, nitrous oxide, methane, and chlorofluorocarbons, by 5.2% from their 1990 levels by 2012 (Coogan, 2006). The European Union and its member states ratified it in 2002. The United States is not a party to the Protocol.

The European Community has been developing a comprehensive sustainable development policy since before the beginning of the twenty-first century. The Amsterdam Treaty of 1997 established sustainable development as a central objective of the Union. In 2001, the European Union adopted its first Sustainable Development Strategy at the Gothenburg Summit. In 2005, the European Council adopted a Draft Set of Guiding Principles for Sustainable Development (European Community's Principles for Sustainable Development, 2005), which recognized the international dimension of a commitment to sustainable development and, in June 2006, it adopted a renewed Sustainable Development Strategy. It recognizes that sustainability extends beyond purely environmental concerns to embrace social equity, reduction of poverty, respect for the needs of developing countries, employment policies, improved education, the rule of law, and social justice.

A Comprehensive Sustainability approach, such as is embodied in the European Sustainable Development Strategy, adopted in 2006 (European Union Sustainable Development Strategy, 2006), and supplemented in 2009, identified 11 key issues:

1. Establish Climate Change and Energy Policy.
2. Promote Sustainable Transportation Modes.
3. Promote Sustainable Production and Consumption.
4. Conservation and Management of Natural Resources.
5. Improve Public Health.
6. Facilitate Social Inclusion, Demography, and Migration.
7. Reduce Global Poverty and Face Sustainable Development Challenges.
8. Improve Education and Training.
9. Research and Development: Encourage research into sustainable development, economic growth, life cycle analysis, and risk analysis.
10. Develop Innovative Strategies to Move toward Sustainable Development.
11. Develop and Refine Indicators of Sustainability.

The 2009 Copenhagen talks on Green House Gas Reduction were inconclusive. The delegates from 190 nations who met in Cancun in December 2010 did not reach any broad agreement on steps to be taken to counteract climate change, but they did agree on a number of matters. For instance, developed industrial countries would contribute $30 billion over the next 2 years to help countries that are most vulnerable to the negative effects of climate change to reduce those effects. It is too soon to know what the effects of the Cancun Agreements will be, but a report by the United Nations Environment Program (United Nations Environment Program, November 2010) concluded, after a careful analysis of over 220 projections of GHG production, that the Copenhagen agreements would not be sufficient to meet the goal of limiting the increase in average global temperature to the 2 °C stabilization target.

In late 2011, the 17th Conference of the Parties met in Durban, South Africa, to address the next steps following the 1997 Kyoto Protocol of the United Nations Framework Convention on Climate Change. The final agreement committed the participating nations to work toward an agreement for the post-2020 era on steps to slow climate change. It launched the Green Climate Fund to support mitigation and adaptation in developing countries. It also clarified procedures for measuring, reporting, and verification of participating countries' climate efforts (Center for Climate and Energy Solutions Report).

In June 2012, over 50 000 people participated in the United Nations Conference on Sustainable Development (referred to colloquially as Rio +20) in Rio de Janeiro. While the conferees adopted a 283-paragraph agreement, 'The Future We Want' (The Future We Want, 2012), they made few if any new commitments to action. One-third of the agreement reaffirms earlier decisions and principles. Another portion confirms goals that should drive nations' activities, such as protecting the rights of indigenous peoples and promoting food security. The rest of the document stresses areas of heightened concern such as conservation of ocean biota, promoting sustainable production, and provision of potable water supplies. While the nations agreed only to develop a new set of sustainable development goals by 2013 (Rio +20 Summary), over 700 voluntary commitments were made by an assortment of nongovernmental organizations, governments, and private corporations that may result in more than $500 billion in expenditures promoting sustainable development (UN Rio +20 Conference Report). Among the most important of these private commitments were 'The Business Day,' which recognized the importance of the contributions of business corporations to sustainable development; 'the World Conference on Justice, Governance, and Law for Environmental Sustainability,' which recognized the central importance of the Rule of Law in achieving a sustainable society; 'the Global Initiative for Resource Efficient Cites,' which recognized the more than half of the people in the world live in cities that offer major opportunities for greater energy efficiency and more sustainable development; 'Global Insurance Principles,' which will promote Principles for Sustainable Insurance; and 'Sustainable Energy for All,' which will promote efforts to achieve sustainable energy by 2030 (Rio +20 Evaluation).

The Intellectual Context of Environmental Planning

As we have noted above, in the process of the shift to the new paradigm of sustainable development, environmental planning has been incorporated as a key element in many aspects of the broader efforts to achieve more sustainable development. Significantly, the locus of planning activities has broadened from primarily national governments to include provinces, states, corporate enterprises, and major institutional actors such as universities. Thus, environmental planners play important roles in:

1. Comprehensive growth management seeks to advance a broad spectrum of goals and objectives. It addresses the location, density, use, height and bulk, and phasing or timing of urban development and redevelopment, and the provision of various infrastructural systems. At the same time, it seeks to protect critically important natural resources, such as farmland, floodplains, marshes, and other areas of critical ecological concern. Comprehensive planning takes into account the underlying geology of the area, the impact of proposed development on groundwater, rivers, lakes, wetlands, and coastal waters, the impact of manufacturing and transportation activities on air quality, the effects of urbanization on the natural biota, the impacts of suburban development on the supply of prime agricultural land, and the effects of solid and liquid waste disposal on the natural environment. Environmental planning is a key component of comprehensive growth management.
2. Environmental pollution control policies are broadly concerned with air, water, and earth pollution, and such global problems as loss of biodiversity, global warming, and depletion of the stratospheric ozone level. Decades of contemporary efforts to protect the environment and reduce environmental pollution have confirmed the oneness of the mankind/natural environment system. Changes in the natural environment can cycle back and cause serious harm to mankind. Transportation, land development, and land use affect environmental quality, whether it be by covering over wetlands, changing the hydrological characteristics of watersheds so as to increase flooding and aggravate drought conditions, converting farmland to residential developments and shopping centers, or creating an automobile-dominated transportation system that generates a major proportion of dangerous environmental pollutants.
3. More efficient generation and use of energy leading to significant reductions in the use of nonrenewable energy sources and in the emissions of GHGs requires environmental planning in the areas of land development, materials conservation, building design, indoor environmental quality, transportation (including the design of more efficient automobiles, the increased use of renewable fuels, and the increase in the use of mass transit), the use of more efficient production systems, supply chain management, and life cycle analysis to reduce the lifetime impacts of different products on the natural environment, and the conservation and management of natural resources.

Research Issues and Major Categories of Environmental Planning

In the field of environmental planning, there are a number of areas of research that are attracting interest from academicians and practitioners. Especially since 2000, environmental planning, often primarily for the purpose of making operations more sustainable, occurs at the various levels of government, in a growing number of private institutions and nongovernmental organizations, and in business corporations.

Research on the Scientific Basis of Environmental Planning

Considerable work is being done in the natural sciences and ecology, generally, to strengthen the scientific underpinnings of an effective environmental planning effort. Some subjects range is fairly specific, such as determining a river's flood plains for differing flood recurrence intervals, or developing more cost-effective ways to remediate polluted industrial sites. Others are much broader, such as determining the extent to which the emission of GHGs from human activities is a substantial cause of global warming, the rise of sea levels, and the increasing violence of weather patterns. The growing emphasis on sustainable development has led to a substantial increase in the benchmarking of building energy consumption and the design of more efficient means of heating and cooling

buildings, the development of more efficient automobile engines that either use a renewable form of energy or are more efficient in their use of nonrenewable forms, the discovery of better ways to minimize raw material consumption in manufacturing processes, to recycle waste products, and to dispose of the remaining wastes in an ecologically protective manner. As nations come to recognize the true extent of global warming, they are exploring ways of planning how best to adapt to the environmental changes occasioned by the process, in the event that they are not able to deduce the rate of climate change significantly.

Environmental Planning by Governmental Agencies

Environmental planning embraces more than the various studies that environmental planners perform in the process of preparing a comprehensive plan or a more specific plan for making buildings more energy efficient or reducing the GHG emissions of transportation systems. It includes a careful assessment and selection of the most appropriate strategies of implementing the various goals of environmental planning and protection. Over the years, the Congress of the United States, for example, has created a virtual arsenal of methods for achieving environmental objectives (Plater et al., 2010). These are grouped in the taxonomy that follows.

A Taxonomy of Strategies for Implementing Environmental Plans

1. Strategies based on disclosure. Environmental assessment and impact statements covering proposed projects such as those mandated by the United States' National Environmental Policy Act of 1969 (NEPA), and numerous state counterparts, with respect to major governmental programs have a significant effect on the environment. This enables affected governmental agencies and citizen groups to find out about proposed actions and to assert their influence to modify their outcome. The technique has been extended to require business corporations to make disclosures of, for instance, the types of hazardous substances they are storing in their plants (required by the Emergency Planning and Community Right to Know Act).
2. Planning strategies. These include requirements for comprehensive planning, critical areas management such as floodplains or important marshes, facility siting laws for power plants and other possibly unwanted land uses, and resource management laws.
3. Strategies based on increased intergovernmental coordination, often accompanied by greater public participation in the decision-making process. For instance, the American Intergovernmental Coordination Act and NEPA call for collaboration among the various governmental agencies with responsibilities in a particular region.
4. Command and control strategies. These approaches have long been the workhorse of environmental planning and protection. A government establishes a regulation that restricts private activity, such as a floodplain zoning ordinance or a statute seeking to reduce air pollution by setting permissible emission levels. This regulation sets a standard with which the private actor must comply, and then applies sanctions to those who violate the standard. Command and control strategies may take a number of forms: (1) from the simple specification of certain environmental standards to harm-based strategies that set standards designed to protect the public health (such as the Clean Air Act's National Ambient Air Quality Standards for key pollutants), (2) technology-based strategies that require the installation of specified technology or technology that achieves a specified level of pollution reduction, (3) technology-forcing strategies, (4) roadblock strategies that prohibit certain activities such as the Endangered Species Act's prohibition of government programs that harm endangered species or destroy their habitat, (5) strategies for controlling market access, prohibiting certain kinds of actions, and requiring that firms internalize formerly externalized environmental costs, and, finally, (6) remedial liability strategies such as those of the Superfund Law that imposes strict, joint, and retroactive liability on any party that has contributed hazardous wastes to, or owned, a Superfund Site.
5. Strategies based on market-based incentives. Many American jurisdictions have experimented with techniques that seek to influence private actors' behavior by providing economic incentives or disincentives that induce citizens to change their behavior simply because it is more profitable. The 1990 amendments to the United States' Clean Air Act established a system for trading emissions allowance for oxides of sulfur (SO_x) and nitrogen (NO_x) that permit electric utilities to meet statutory requirements either by reducing their emissions by installing more effective air pollution control devices or by buying emission rights from other producers, whose emissions are well below their assigned level.
6. Tax expenditures. Many nations have created tax incentives that seek to increase after-tax income of individuals and companies that engage in conduct that is either environmentally protective or environmentally enhancing. Tax expenditures are variations from the normal structure of a particular tax designed to influence a business or individual's behavior by increasing its or his after-tax profits, such as investment tax credits for the installation of insulation, or more energy-efficient heating or cooling equipment.
7. Spending strategies. These strategies include grant-in-aid and loan programs, such as the United States $60 billion program for the construction of Publicly Operated Waste Water Treatment Plants under the Clean Water Act.
8. Demand management strategies. A number of programs seek to control demand for a particular product or facility, such as bottle return fees for soft drink bottles, high occupancy vehicle lanes, and parking limitations in congested or polluted areas.

Environmental Planning by Cities

Dozens, if not hundreds, of cities around the world are often undertaking voluntary programs to develop and implement strategies for reducing the emissions of GHGs and for making both municipal and private activities more sustainable, in an effort to reduce climate change and make their operations more efficient. In most cases these efforts started after 2000. They are best exemplified by the creation in 2005 of the C40 Cities Climate Leadership Group (C40). In 2011, it became fully

integrated with former President Bill Clinton's Climate Initiative Cities Program in the Carbon Disclosure Project, and received a major grant from the Bloomberg Philanthropies (C40 Cities). C40 Cities was created to reduce carbon emissions and to increase energy efficiency of large cities around the world. In 2011, its C40 Cities Climate Leadership Group counted 58 major cities as members from every continent, including Sydney, Tokyo, Beijing, Jakarta, Delhi, Cairo, Johannesburg, Moscow, Berlin, Paris, London, Bogotá, Buenos Aires, Mexico City, New York, Chicago, Los Angeles, and Toronto (C40 Cities, KPMG Report, 2011). The CDP 2011 Global Report on Cities was based on a questionnaire sent out to 64 cities to which 48 responded. It estimated that about 12% of the world's carbon emissions were produced in its cities' metropolitan areas and roughly one-eighth of the world's population lived within their limits (C40 Cities).

The CDP 2011 Global Report permits a number of generalizations. Many of the world's major cities are located in coastal areas and are particularly vulnerable to rising sea levels and more violent weather events that result from global warming. Thus, they have special incentives to begin to understand the nature and extent of their GHG emissions and to start finding ways to reduce emissions from both municipal and private sector and community facilities and operations. Their efforts have been focused in three major areas: (1) governance and planning, (2) GHG measurement and management, and (3) climate change risk assessment and management.

In many cases GHG emissions control was incorporated into regular comprehensive planning activities. Three typical environmental plans for dealing with climate change and a number of related environmental issues are those of New York City (New York, PlaNYC, 2009), Philadelphia (Philadelphia Greenworks, 2009), and London (London Sustainability, 2012). (This is the second edition of London's 2007 plan and it incorporates all of London's sustainability commitments.)

Most cities developed reporting systems for both municipal emissions and community emissions. They used a variety of methodologies to report these data, including spreadsheets and proprietary programs, that are designed specifically for this purpose.

These major cities are taking a hardheaded approach to risk assessment and management of the threats posed by global warming. As indicated above, many consider themselves at risk because of their low-lying coastal locations and are using a variety of different methods to project and assess these impacts on their physical structure and economies. Few of the cities have actually implemented their environmental plans for adapting to the anticipated risks because of the very novelty of the process of assessing climate change risks.

The CDP Report, *Cities 2011: A Global Report on C40 Cities*, reveals strategies and action programs that were still in their very early stages. Most have been undertaken since 2006. They show a need to (1) improve and standardize GHG measurement methodologies; (2) accelerate the development of data management software; (3) develop financial forecasting related to climate change investment; (4) create better tools for city-level risk assessment; (5) develop practical strategies and programs for reducing carbon emissions in both municipal and community sectors; and (6) perfect ways of monitoring progress in meeting programmatic goals (C40 Cities KPMG, CDP Report, 2011).

Many of the steps local governments can take are summarized in the United States Environmental Protection Agency's *Sustainable Design and Green Building Toolkit* (USEPA Toolkit, 2010). Buildings account for 40% of total energy consumption, 13% of water use, and 160 million tons of construction and demolition debris per year. More difficult to quantify but nevertheless significant are the effects of urban sprawl and its extensive land development patterns, Brownfield remediation, and loss of prime farm and forestland. The EPA's Sustainable Design Toolkit identifies five major aspects of land development and building construction that have impacts on the sustainability of communities. These categories have, in turn, a number of subcategories, each of which has its sustainable design objective, rationale, and overarching question. The report suggests strategies, tools, and techniques for engaging in environmental planning that will increase the level of sustainability for each of the categories and subcategories. The five categories are as follows:

1. Sustainable Sites and Responsible Land Development: This category addresses the development and minimization of the negative effects of land development and the impact of buildings on the natural environment.
2. Materials and Resource Conservation: This category examines ways of minimizing waste from construction sites and the use of green materials during construction.
3. Energy Conservation and Atmospheric Quality.
4. Water Efficiency, Conservation, and Management: This category addresses buildings' water consumption and ways of minimizing its impact on the environment.
5. Indoor Environmental Quality: This category addresses methods of improving indoor air quality.

Distributed and Often Voluntary Environmental Planning by Large Institutions and Business Corporations

Environmental Planning by Universities and Colleges

One of the remarkable developments during the first decade of the twenty-first century has been the decisions by hundreds of colleges and universities around the world, but especially in the United States, to undertake serious efforts to develop Climate Action Plans that will enable the institutions to reduce their GHG emissions. Most of these programs were adopted after 2000. In 2007, The American College & University Presidents' Climate Commitment organization (ACUPCC, 2007) prepared a document for signature by university and college presidents that committed the institution to agree to initiate two or more of seven actions designed to reduce GHG emissions within 2 years after their implementation start date. These actions included, for instance, (1) adopting a policy that all new campus construction would be built at least to the United States Green Building Council's Leadership in Energy and Environmental and Design (LEED) silver standard or its equivalent (USGBC LEED Program, 2012), (2) committing to begin purchasing at least 15% of the institution's energy consumption from renewable sources within 1 year of signing the commitment, and (3) adopting an energy-efficient appliance purchasing policy requiring purchase of ENERGY STAR

certified products in all areas for which such ratings exist (ACUPPC, 2007). By the end of 2011, 674 presidents had signed the commitment (many of whom headed multicampus universities such as the University of California) and 451 institutions had submitted Climate Action Plans. In other countries, many universities have also established significant sustainable development strategies, such as the universities of Oxford, Cambridge, and St Andrews.

In broad outline, a typical Climate Action Plan sets up a series of steps, such as those undertaken by the University of Pennsylvania in its Plan (the University of Pennsylvania CAP, 2009):

1. Undertake a complete inventory of campus emissions and emissions attributable to university activity, measured in metric tons of carbon dioxide equivalent (MTCDE).
2. Project the various types of emission ahead 40 years on the assumption that no actions were taken to reduce them (the 'business as usual' projection), including estimates of newly constructed floor space, and growing energy-consuming activities.
3. Break the total carbon dioxide emissions into different categories and develop strategies for reducing these emissions in each of these categories over a period of 40 years. Penn's environmental planners focused on six strategic areas:
   - Reduction of electric intensity.
   - Design and build new high-performance buildings by using the United States Green Building Council's LEED standards for new buildings and meeting the Energy Star 90 standard of the American Society of Heating, Refrigerating and Air-Conditioning Engineers.
   - Reduction of energy use of existing campus buildings. Improve the efficiency of existing utilities by reducing system losses, insulating steam lines, and repairing stem leaks.
   - Reduce air travel and encourage the use of mass transit and carpooling by students and employees.
   - Purchase Renewable Energy Credits. A Renewable Energy Credit represents and conveys the environmental and other nonpower attributes of 1 MW-h of renewable electricity generation.
4. Develop programs in each of these areas for reducing the amount of GHGs produced thereby. The University of Pennsylvania's planners projected 2050 total emissions under the 'business as usual' alternative to be about 600 000 MTCDE. By applying the various strategies outlined above, they estimate that, by FY2050, the MTCDE of each type would be reduced by the following percentages:
   - Reduce electricity intensity – 18%
   - High-performance new buildings – 16%
   - Renovate existing buildings – 27.8%
   - Recommission existing building systems – 17%
   - Improve efficiency of existing utilities – 3.5%
   - Reduce air travel and other emissions – 3.5%
   - Purchase Green Power RECs – 13%

This approach was based on concepts developed by Stephen Pascala and Rob Socolow and presented in an article in *Science* journal in 2004 (Pascala and Socolow, 2004). The University of Pennsylvania's Climate Action Program presents it graphically in Figure 1.

Almost all of the university climate action plans were adopted in the first decade of the twenty-first century. Even in the short time since then, many have evolved to focus on a broader range of environmental protection measures, so that they promote the broader goals of sustainability rather than just those of moving toward carbon neutrality. Typically, they address reduction of carbon emissions, improving energy efficiency, green building for new facilities, waste minimization and recycling, increased transportation efficiency, better use of

Figure 1 The University of Pennsylvania's 'Wedge Diagram' showing how each sector will contribute to reduction of CO_2 emissions.

water, refining food systems, and education in sustainable development policies and operation.

Environmental Planning by Business Corporations

Every business corporation is subject to the environmental protection laws of countries where it operates, such as those governing air pollution, water pollution, solid waste management and disposal, and use and storage of hazardous materials. Reviewing the corporate environmental planning that is involved in complying with those laws is beyond the scope of this article, other than as reviewed in Section Environmental Planning by Governmental Agencies, above.

Largely since 2000, there has been a notable increase in the extent to which private sector corporations have taken issues of sustainability into account in their corporate management and strategies. This growing interest has been evidenced in a number of ways (Feldman, 2009). Many companies have begun to speak of the 'triple bottom line,' which adds environmental and social measures of performance to the traditional financial ones. Others treat it under the rubric, 'corporate social responsibility (CSR),' and still others embrace sustainable business practices in many parts of their operations. Many corporations have created new management positions, such as Vice President for Sustainability or Vice President for CSR (Blackburn, 2007).

Corporations are adopting these policies for a variety of reasons. Most calculate that making their operations more sustainable will reduce energy, production, and marketing costs. Others are doing it because it is good public relations and they want to match shareholders rising expectations. In addition, market analysts are beginning to analyze and disclose corporations' environmental performance (Feldman, 2009; Makower, 2012), so that the investing public has greater access to information on corporate sustainability performance.

Conclusion

In the first few years of the twenty-first century, we have witnessed a remarkable rethinking of man's proper relationship with the natural environment, a process that will have profound implications on the full range of societal activities. For instance, the European Union's 2006 Sustainable Development Strategy addresses several pressing environmental issues, such as climate change, environmental pollution, loss of biodiversity, safe water supplies, energy conservation, building construction, and waste recycling and disposal, but it also addresses broader societal and economic issues such as public health, social inclusion and equity, global poverty, and underdevelopment. Thus, environmental planning is in the process of being reframed as part of more comprehensive strategies designed to achieve sustainability in the broadest sense of the word.

This process of rethinking societal goals is occurring in many different milieux. Most obviously, it is taking place at the ongoing series of international conferences that are addressing climate change and GHG emissions. It is taking place in national legislature after national legislature, and in regional and local governments. Most significant, perhaps, is that many large business corporations and substantial nongovernmental institutions such as universities are also becoming engaged in a broad spectrum of programs and policies that are designed to reduce the environmental impacts of these organizations' activities.

This process is by no means uniform and coordinated. It is fitful and uneven with advances here and retreats there. Because of its novelty, many organizations are only now beginning to face the political and economic implications of the policies and programs they have proclaimed. It is one thing, they are finding, to publish a climate action plan or a strategy for sustainable development. It is quite something else to find the resources and political will to actually implement the program or strategy. It is especially difficult in this time of recession, when income has declined and many needs demand attention, to move environmental, sustainability, and energy efficiency actions up on the list of budgetary priorities, no matter how persuasive are the arguments for protecting the environment and making the activities of the firm, the organization and society as a whole, more sustainable. Only time will tell whether the remarkable explosion in programs for environmental protection and sustainability will result in deep changes in the impacts of human activities on the natural environment.

Abstract

Environmental policy is primarily concerned with how to govern the relationship between humans and the natural environment in a mutually beneficial manner. Traditionally, it has been defined in terms of the problems it addressed, such as controlling pollution and waste flows and limiting habitat loss. However, policy makers have begun to appreciate that environmental policy will only be genuinely successful when it is sensitively integrated with other sectors and policy areas. Politically speaking, 'environmental policy integration' represents a new but potentially difficult stage in the continuing metamorphosis of environmental policy into a much wider policy supporting sustainable human development.

Environmental policy is essentially concerned with how best to govern the relationship between humans and the natural environment for their mutual benefit. This broad definition successfully captures the unbounded character of the environment as a distinct public policy field, touching as it does upon virtually *every* aspect of modern life. However, it lacks specificity: most areas of government policy affect the world 'out there.' A more precise definition is achieved by disaggregating the term into its component parts – i.e., 'environment' and 'policy' – although both are difficult to pin down.

Within politics, 'environment' remains a contested concept. Albert Einstein famously defined the environment as "everything that isn't me." Environmentalists would argue his interpretation fundamentally depersonalizes an inherently subjective, spiritual experience specific to every person. However, they would accept that his implied notion of 'everythingness' is useful as it powerfully confirms the complex and essentially unbounded nature of environmental policy, necessitating responses which are sensitively integrated with the main sectors of society. On this line of reasoning, *every* policy area has environmental implications. But the very 'everythingness' of the environment is why politicians often struggle to address the underlying roots of environmental damage through conventional sound-bite politics and ad hoc policy interventions. In solving environmental problems, politicians have to convince individuals to adapt their behavior for the good of society and future generations – never easy when benefits are diffuse and costs (or benefits foregone) are immediate. Finally, environmental issues raise difficult political, moral, and ethical questions which vote-chasing politicians instinctively avoid, thereby marginalizing environmental issues within mainstream politics.

If 'the environment' is amorphous then the term 'policy' is equally slippery. A dictionary definition is "a course of action or principle adopted or proposed by a government." However, some policies comprise a series of decisions, layered on top of one another. Moreover, policies may be formally adopted by national governments but the details of implementation are often determined by lower levels of government. Therefore, when a local pollution control officer negotiates with a polluting factory over a site license or emissions permit, he/she is arguably 'making' policy. Finally, policies also serve a symbolic purpose. Some are only ever statements of intent which governments have no real intention of enacting. Policy, therefore, should be thought of in terms of courses of action and inaction: as much an ongoing *process* of interaction as a discrete product or output of the political system, written down in legal texts.

Due to these and other conceptual ambiguities, the notion of 'environmental policy' is commonly defined in terms of the problems it addresses. Traditionally, environmental policies have been associated with controlling pollution, limiting natural habitat loss, managing waste, and reducing the impact of natural hazards (Connelly et al., 2012). These policies are normally implemented using regulatory tools although non-regulatory instruments such as taxes and voluntary agreements have become increasingly popular. However, environmental policy, in the broader sense described above, touches upon many more issues, such as food production, energy, transport, human health and safety, consumer choices, the survival of biological species, and even international security. In short, environmental policy addresses the complex, reciprocal links between modern society, the economy, and the environment, making it unique among policy areas (Ingram and Mann, 1983). The recognition that the increased pace, scale, and magnitude of contemporary human activity has pervasively affected the natural environment has been an important driver of environmental policy since the 1960s. Achieving a harmonious balance between society, the economy, and environmental systems is the main aim of *sustainable development*, the key concept for organizing environmental policy (Adger and Jordan, 2009).

The Main Characteristics of Environmental Policy

According to Albert Weale (1992: 5), the objective characteristics of a policy area have an important bearing upon the form of politics and policies that develop around it. This section explores the main characteristics of environmental policy.

Governing Public 'Goods' and 'Bads'

Environmental quality is a classic example of what economists term a nonexcludable or 'public' good. Thus the benefits of

environmental quality accrue to most if not all citizens (or, to put it another way, the costs of degradation are borne by society rather than just the polluter). This seemingly self-evident observation has important implications for the scope of environmental policy. First, large parts of the environment – the atmosphere and open oceans – are common property and nobody can be excluded from using them. While the benefits of resource use tend to be concentrated spatially, the costs or 'externalities' are typically dispersed across myriad individuals in the form of pollution (or economic 'bads'). Think of a smoking factory chimney pouring black soot onto surrounding houses. Here, the polluter has an economic incentive to continue consuming clean air knowing that the bads will be borne by the whole neighborhood. Second, while the financial cost of improving the environment often falls on one small section of society (e.g., the factory owner), the benefits are normally spread among myriad users. Polluters, who have a strong incentive to unite and fight to protect their pollution rights, have an advantage over those suffering the disbenefit. The latter are often too widely dispersed or individually suffer too little to mobilize effectively. Third, those fighting for the 'public' interest or the welfare of natural entities do not necessarily act automatically to achieve their individual or group self-interests. Mancur Olson (1965) argued that individuals have an incentive to 'free ride' by consuming environmental quality in the hope the cost will be borne by some other party or society as a whole. For example, polluters of a stream will continue to pollute hoping that a sufficient number of others desist from polluting it. However, the public good aspect of environmental problems also conditions attempts to abate environmental damage. Then, recreational users of our hypothetical river may well calculate that it is easier to free ride (i.e., wait for someone else to tackle the polluter and share in the benefits of clean water) than do something themselves. One reason why motorists continue to drive is that they cannot easily be excluded from the benefits (i.e., less air pollution and congestion) which are generated when some give up their vehicles and turn to public transport. This collective action problem is further developed in Garrett Hardin's (1968) famous parable of the 'tragedy of the commons.'

The Need for Regulation

Because environmental damage originates in otherwise socially legitimate activities like energy and food production, the state is often forced to police the consumption of public goods by limiting the damages that one section of society can impose upon others. Environmental policy is therefore inherently *regulatory* in nature, although regulation inevitably has distributive and redistributive consequences (Lowi, 1972). Lowi argued that whereas distributive policies (e.g., welfare programs) produce a close, dependence relationships between the state and interest groups, regulatory policies produce more conflictual politics as they force polluters to adopt costly abatement measures. However, not all interest groups enjoy the same level of influence or political power. Some routinely have more say than others in determining the content of policy by 'capturing' the regulatory process, although the influence of sectional groups is hotly disputed among political scientists (Dryzek and Dunleavy, 2009). Business groups do, however, enjoy a structural advantage over other groups – one which exacerbates the collective action problems suffered by environmental groups. According to Lindblom (1977), as *all* governments, whether Left or Right, need a healthy economy to provide jobs and welfare support, they have to adopt business-friendly measures without business having to take any observable action. Scientists too have their own independent policy objectives, and can be considered a kind of interest group. In some situations 'epistemic communities' (Haas, 1992) of scientific experts have decisively influenced policy by steering decision-makers.

Coping with Complexity and Uncertainty

Once human development exceeds the planetary capacity for self-repair, environmental assets can collapse and disappear, never to reappear. Admittedly, some environmental assets and functions are repairable or substitutable (individual trees can be replanted; water can be transported), but many others (a delicate wetland habitat for example) are not. Irreversibility complicates environmental policy making, differentiating it from more easily revisited areas such as tax or social affairs. Irreversibility implies that piecemeal policy responses should be substituted for ones that foresee problems and address them systematically. In practice, the environment often responds slowly to human interventions, and 'local' problems are sometimes only the observable tip of much more complicated and spatially dispersed processes. For instance, the pressure to pollute a local river with fertilizers may stem from a national policy to intensify agricultural production in order to compete in world markets. This raises the question of how decisions should be made at one level when consequences for other levels or sectors cannot be easily predicted. Should decision-makers err on the side of caution or proceed hoping that unfavorable consequences will not arise? This is one reason why the precautionary principle – the idea that policy makers should go 'beyond science' to address potential problems when the threat of harm is significant and potentially irreversible – has become important to policy debates in areas such as genetically modified food. But whenever environment impacts cannot be precisely determined, opportunities arise for vested interests to twist scientific ignorance to suit their own cause. Political systems also struggle to cope with genuine uncertainty; hence difficult environmental policy decisions are routinely handed to expert committees to deliberate upon, delaying still further the adoption of protective measures.

Governing through Time and Space

Although environmental quality is a classic example of a public good, the costs and benefits of policy do not necessarily accrue to the same citizens. Consequently equity and justice are central to most, if not all, environmental decisions. Those who suffer most from environmental damage are often the poorest and most vulnerable, while others who benefit have a vested interest in maintaining the status quo. The precise spatial and temporal distribution of costs and benefits produces alliances of self-interest which battle to determine

the scope and content of environmental policy. Constructing a bypass road around a congested village, for example, will greatly improve the welfare of its residents but at the cost of disruption to those in the path of the alternative route. Balancing these different needs becomes a central question of *politics* (or decision making) which is pervasive in all environmental policy making. Another problem facing policy makers is how to account for the well-being of future generations whose needs can only be anticipated. According to the most widely adopted interpretation of sustainable development, articulated in the UN Brundtland Report (WCED, 1987), policy makers should address the needs of current generations of humans without compromising the ability of future generations to meet theirs. Clearly, this raises thorny questions of justice and morality, to say nothing of due democratic process.

Governing across Political Borders

Unfortunately for policy makers, environmental problems show scant regard for political borders. Essentially, there are three types of international problems. The first arises when the legitimate activities of one state have international implications (e.g., global warming). Then there are global processes such as trade and international debt which have environmental implications. Finally, there is the problem of how to preserve resources such as rainforests and regional seas that reside in one part of the world but are valued by all. Olson's theory of collective action again illuminates the difficulties in achieving cooperation, this time between states rather than individuals. Regional arrangements, such as those pioneered in the European Union, provide the best evidence of successful international diplomacy (Jordan and Adelle, 2012). However, many disputes about responsibility for causing and remedying global environmental problems such as global warming hinge on a North-versus-South axis, though not exclusively so. In these circumstances, environmental policy relies upon regimes – i.e., international conventions and protocols – to build trust between participants. Many regimes have been negotiated since the 1970s (see Connelly et al., 2012). In some circumstances, they have been deliberately designed to offer 'selective incentives' (Olson, 1965) (i.e., technical and financial assistance) to incorporate reluctant countries, whose participation is nonetheless vital for success.

Integrating across Policy Areas

While the environment functions as an integrated whole, the bureaucracies managing it are typically fragmented in order to avoid administrative overlap and inefficiency. The mismatch between institutions and environmental problems has been an enduring problem for policy makers. The environment is probably unique in how it crosscuts traditional government sectors. In consequence, environmental policy making often produces furious conflicts between environmental ministries and more powerful parts of government representing finance, agriculture, transport, and so on. Accordingly, one of the great unmet challenges since the 1990s has been to *integrate* environmental concerns into these areas (Jordan and Lenschow, 2008). According to the UN Brundtland Report which set the terms of the international debate about sustainable development:

> Those responsible for managing natural resources and protecting the environment are institutionally separated from those responsible for managing the economy. The real world of interlocked economic and ecological systems will not change; the policies and institutions concerned must.
>
> WCED, 1987: p. 9

Often each department defends its own position while resisting a line that, while potentially beneficial to society as a whole, clashes with its 'own' interests. So even if the environment department wishes to push a greener line, it is likely to encounter fierce opposition from departments representing commercial interests (Jordan and Lenschow, 2008; Jordan and Schout, 2006).

Dealing with Nonhuman Entities

Environmental policy is probably the only policy domain which has the main goal of protecting nonhuman entities. Although most people support environmental protection the crucial question is to what extent should moral significance be ascribed to plants and animals, especially if it involves self-sacrifice and higher economic costs? There are essentially two ethical positions in an ongoing debate that underpins most environmental policy making: technocentric and ecocentric. Those who adopt a *technocentric* view regard nature as a source of resources to be exploited, whereas ecocentrists feel that the nonhuman world has interests and moral significance independent of human valuation – what economists term 'existence value.' While the technocentric view is hierarchical, manipulative, and managerial, the ecocentric view, by contrast, embraces community scale, natural rhythms, and a morality based on ecological principles. Business tends to adopt a more technocentric line, which conditions policy via the structural commitments outlined above. The 'green' case put by environmentalists is much more ecocentric. If anything, after decades of debate interests have converged on the center of this continuum of worldviews. Indeed sustainability – at least as defined by the Brundtland Report – has proven to be politically palatable precisely because it maintains that the world *can* grow its way out of ecological crisis.

Despite this convergence, contemporary environmental conflicts are still driven by the clash between worldviews. We see this in debates about genetically modified organisms and foods. The large chemical companies are largely technocentric, stressing the benefits of manipulating natural processes for human benefit. Their faith in the power of science to achieve a transition to modified crops in a predictable and controlled manner sets them apart from environmental groups who stress the fundamental uncertainties involved – which, if not respected, may result in irreparable damage to biodiversity. Informing this debate is the question of whether humans have the moral *right* to 'play God' with nature. The technocentric has few moral qualms about this, whereas the committed ecocentric does.

The Main Elements of Environmental Policy

A Brief History of Environmental Policy

As policy areas go, environmental policy is relatively youthful, dating back only as far as the early 1970s. Environmental provisions existed before that time but were relatively fragmented, aimed mainly at securing human health, and developed in a reactive and ad hoc manner. Environmental policy gained its impetus from the great upsurge of public interest in environmental matters during the late 1960s. Landmark books such as Rachel Carson's *Silent Spring* and *Blueprint For Survival* by the Ecologist magazine suggested a global crisis was imminent – a message which found receptive audiences in the US and Western Europe. The first evocative images transmitted from the space of Earth floating precariously in the inky blackness of deep space helped catalyze and intensify public concern. The unprecedented magnitude of human-induced environmental change throughout the twentieth century had also produced an objective reduction in environmental quality. Many national environmental ministries and the United Nations Environment Programme (UNEP) date from this period (Jänicke and Weidner, 1997). The policies adopted were mainly regulatory, specifying processes and emission standards. In those countries with less developed administrative systems, this early period saw the development of basic standards for air, water, waste, and noise pollution.

Another feature of this era was the growing internationalization of policy noted above. Early environmental regimes were often regionally based, such as UNEP's 1976 Barcelona Convention for protecting the Mediterranean (Connelly et al., 2012). More globally encompassing regimes then appeared in rapid succession to counter inter alia marine pollution, acid rain, ozone depletion, and hazardous waste shipments. During the 1990s, a new phase of international policy making emerged from agreements made at the United Nations Rio Earth Summit (1992). Most significantly, a UN Convention on Biological Diversity and a Framework Convention on Climate Change were agreed, the latter subsequently supported by the Kyoto Protocol (1997) aimed at limiting global climate emissions.

As sustainable development became the main discourse of environmental policy, the focus shifted from dealing with environmental damage – pollution, waste, and habitat loss – to addressing the underlying causes. The trend toward redesigning institutions and organizations to tackle problems at root is often labeled *ecological modernization* (Mol et al., 2009) – a political philosophy reflecting a technocentric view of sustainability. This involves moving from setting end of pipe standards to tackling social processes that generate emissions. The shift toward more diffuse and less interventionist policy tools in part reflects political pressure from business for more flexible and economically efficient alternatives to regulation. The 'new' tools in the armory of environmental policy now include (Wurzel et al., 2013):

- *Ecolabels*: These signal the environmental impact of products and processes to purchasers and investors. Eco-auditing and lifecycle assessments help to rate the eco-friendliness of products and processes by measuring their overall environmental impact.
- *Eco-tax reform*: Working with the grain of markets, taxes are designed to penalize economic 'bads' and, through hypothecation mechanisms, reward 'goods' such as labor. For example, in 1997, the UK adopted a tax on the waste deposited in landfills, the revenues from which are diverted to environmental projects.
- *Environmental assessment*: The aim here is to implement the principle of environmental policy integration. The US National Environmental Policy Act (1969) formally required an environmental assessment of individual development projects such as power stations. Although project level environmental impact assessment has since become accepted worldwide, more recent approaches to integration involve the 'strategic' assessment of higher level policies, plans, and programs.
- *Integrated product policies*: Using various devices to 'green' the production of goods from their design and production, through to final disposal. A good example is the EU's packaging waste directive which aims to reduce the overall quantity of waste material.
- *Strict liability regimes*: By making developers legally responsible for remedying the damage they cause, these encourage a more consistently preventative approach to environmental issues.

To these instruments, we might add resource-use policies that seek to transition economies toward greater sustainability. For example, the Japanese government promotes a '3R' policy of reduce, reuse, and recycle through multiple policy instruments, with an emphasis on avoiding environmental problems at source.

Climate change has emerged more forcefully as a policy issue at multiple levels since the late 1990s. A global 'leader' in this respect is the European Union, which has introduced a suite of innovative policies for climate mitigation, most notably an emissions trading system (Jordan and Adelle, 2012). Policy responses from national governments worldwide have been more mixed. Pioneering national legislative measures such as the UK Climate Change Act, that establishes legally binding annual emissions reduction targets, can be contrasted with the relative inaction of states such as the US where climate change has effectively become a policy nonissue at the federal level. This difference in national perceptions has slowed down the ongoing development of the Kyoto Protocol.

National Policy Styles

When studying these political responses to environmentalism, states and supranational organizations have evidently followed different paths reflecting their history and political mandate. The current allocation of responsibilities generally respects the principle of subsidiarity, whereby problems should be addressed at the lowest appropriate level. Global problems are addressed at the global level (i.e., the United Nations), regional problems at the regional level (e.g., the EU), and the rest at the national or subnational level. Environmental pressure groups and scientists have learned to work at all levels, removing environmental policy from the domain of purely state-guided action and placing it within a multilevel system of governance (see Jordan and Adelle, 2012).

In spite of internationalization, individual states continue to pursue different approaches, reflecting their individual geographical circumstances, political and constitutional makeup, cultural orientation, and economic conditions (Jänicke and Weidner, 1997). The interaction of these circumstances gives each country a distinct national 'policy style' (Richardson, 1982) which preexists its response to new political issues. Since the 1980s, Germany has adopted an anticipatory approach based on explicit standards and programs which are designed to 'force' the development of clean technologies. German approaches contrast starkly with the open, conflictual, and rule-bound nature of the US political system where the importance of the free market partly explains why the US has gone furthest in experimenting with economic instruments such as tradable permits.

The Policy Process

The policy process is normally conceptualized as sequential parts or stages. These are (1) problem emergence, (2) agenda setting, (3) consideration of policy options, (3) decision-making, (5) implementation, and (6) evaluation (Jordan and Adelle, 2012). According to this 'textbook' view of policy, environmental groups must first get a particular problem on the agenda for discussion and, if possible, consideration by policy makers. Policy makers then select the best course of action based on specialist advice, make the policy, then hand it to administrators for implementation. This stage-based view emphasizes that policy is a process involving many different parts of government. But in practice, policy issues are interconnected, policy makers fumble around for solutions in the context of great uncertainty and many internal and external constraints. Past practice often has a determining effect on how new issues are processed. To counter such uncertainty, increasing use is being made of scientific evidence to guide environmental policy development. Multiple policy 'tools' such as expert reports, consultation, and cost–benefit analysis are employed by governments to provide such decision support (Jordan et al., 2015).

A multitude of different models and theories have been developed to explain policy making (see Hill, 2009; Dryzek and Dunleavy, 2009). One strand is pluralist in its assumptions. *Pluralists* believe that political power is widely, although unevenly, spread throughout society. Although powerful groups exist in particular policy sectors, no single group is continuously capable of shaping the entire policy process. In policy terms, pluralists assume that agenda setting is open and competitive, with the government acting as an honest broker. Once adopted, though, policies must still be steered through the implementation process. Because of the competitiveness of the policy process, outcomes are unpredictable.

Neo-pluralists meanwhile argue that business occupies a 'privileged' position compared to other groups. Instruments like the mass media help to structure environmental politics by removing 'grand majority' issues concerning the fundamentals of the political order from the agenda, leaving citizens to debate residual 'secondary' concerns (Lindblom, 1977). Whereas pluralists assume that grievances are openly debated, neo-pluralists argue that they are organized out of politics by institutional rules and routines. Policy making occurs within small and stable groups of actors (or networks) clustered around particular government departments. Policy outcomes then generally reflect business preferences rather than those of environmentalists, who find it difficult to access decision-makers or are deterred from even trying.

Finally, *structuralists* believe that the state is under powerful structural pressure to nurture economic growth regardless of the environmental implications (Benton, 1996). On this view, most environmental controls are nothing more than a sham, introduced to pacify critics and keep the conflict between economic classes to manageable levels. For Marxist scholars, environmental problems are rooted in the unequal distribution of resources within society. There can be no lasting solution to such problems until the social system is structured more equally.

What Drives Environmental Policy and Politics?

Having defined the policy process and the main tools used, the obvious question is what actually drives it forward? Where do the inputs, or political issues, come from which create the agenda for environmental policy making? The answer is partly conditioned by which of the three models described above is used. These differences notwithstanding, ultimately the source of all green ideas is environmentalism, a broad social movement which emerged in the late 1960s reflecting a growing public demand for a better environment (Doyle and McEachern, 2007). Environmentalism, the roots of which stretch far back into the past, is reflected in a long-term shift in public opinion toward 'quality-of-life' issues, and an increasingly active and diverse range of 'green' pressure groups. Environmental concern has exhibited a broadly cyclical pattern over time, with particularly pronounced peaks in the late 1960s and 1980s. Closer scrutiny reveals that these short-term pulses coincided with periods of economic growth and social introspection.

Downs (1972) produced a simple model that captures these dynamics. He argues that environmental issues evolve slowly in a culture of scientific enquiry and suppression. This is usually a fairly secretive phase during which gloomy prognoses are carefully explored away from the glare of media concern. The second phase in his 'issue attention cycle' was one of media attention and anxiety. Since the 1960s, the environmental movement has benefited enormously from successive crises including Seveso, Three Mile Island, Chernobyl, and Fukushima. The third phase is the reactive process in which political institutions cope and adapt. During the fourth phase the costs of protection sink in, and demands grow for regulation to be dismantled to allow enterprise and economic growth. The so-called contrarians begin to question the accuracy of environmental claims (North, 1995). However, downgrading environmental protection succeeds only in propagating the next crisis, and so the cycle begins again.

Environmental policy has generally followed these oscillations. The early 1970s and the period 1989–92 were thus both marked by important institutional innovations. The respective focal points were international conferences at Stockholm (1972) and Rio (1992). In turn, these triggered public and private awareness, much greater financial investment, and

corporate planning. Significantly, however, political concern has not settled back to the original level, but has oscillated upward around a steadily rising curve. Ratchet-like, the laws and public institutions established to protect the environment during each upsurge, have helped fix environmental values, providing a new platform for subsequent policy making.

Conclusion

Environmental policy has reached a critical stage in its relatively short life. In the 1970s, governments across the world responded to the rise of environmental values by establishing agencies and laws to address specific issues as and when they arose. Policy makers regarded environmental problems as essentially technical in nature; policies were overwhelmingly reactive rather than proactive, and sectoral rather than integrated. But starting in the 1980s, the discourse surrounding environmental issues began to center on the concept of sustainable development (Adger and Jordan, 2009). Significantly, sustainable development is not simply economic advancement 'greened' by bolting on cleaner technologies and reducing waste, but a *process* of human development which simultaneously satisfies social, economic, and environmental goals, within and between different generations.

The emerging orthodoxy in the twenty-first century is that environmental thinking must be integrated into areas of policy traditionally regarded as 'non'-environmental such as agriculture, transport, and energy (Jordan and Lenschow, 2008). One important lesson learned in the last 40 years is that the fundamental driving forces of unsustainable behavior reside in these sectors. Unless these forces are addressed at their roots, environmental protection will always be reactive, piecemeal, and ad hoc. Politically speaking, the transition to environmental policy integration represents a new and potentially difficult stage in the continuing development of environmental policy. However, the political stakes are high because by greening other policy areas, environmental policy is in effect progressively undermining its own, hard-won independent existence. The irony is that if the environment is reflected fully in every aspect of policy making, there will be no need for an identifiable 'environmental' policy. Whether this outcome is ever likely to occur in practice, however, remains open to discussion.

Abstract

It is important to distinguish between ecological risk assessment and risk evaluation. Assessment includes all systematic approaches to understand the consequences of human interventions into the natural ecosystem and to calculate the risks for potential damages. Risk evaluation includes the process of judging the acceptability of these interventions on the basis of a comparison between the expected benefits and risks. Both tasks require sound knowledge and ethical judgments. Judgments about acceptability are contingent on the priority of human values and social development goals. This is the reason why such judgments need a democratic legitimization based on an inclusive judgment and decision process incorporating representatives from science, politics, economics, and civil society.

Introduction

Environmental risks refer to the possibility or probability of negative impacts associated with human interventions into nature (Dobler et al., 2014: 2). Interventions are normally taken for resource depletion or using the natural environment as a sink for waste in all its forms. Risks stemming from these interventions include damages to human health, environmental quality, ecosystem functioning, changes in landscape, and loss of biodiversity.

Most interventions involving environmental risks to humans or nature are made for some reason: the actors who make such interventions want to secure goods or services to consumers, for example, to ensure long-term jobs and adequate incomes, to use natural resources for products and services, or to use nature for recycling waste materials from production and consumption that are no longer needed. None of these are done for reasons of brotherly love, but to maintain social interests. The list of human activities that pose risks onto others perpetrated for existential or economic reasons could be carried on into infinity. Human existence is bound to taking opportunities and risks (Radandt et al., 2008: 212).

With today's settlement densities and the predominantly industrial way of life, the human race is dependent on the technical remodeling of nature. Without doubt, human societies need interventions into the natural environment not only for survival, but also for the well-being of the innumerable people, goods, and services that reduce the stock of natural resources. With regard to the question of the acceptable risk level that human interventions in nature can cause, the question cannot be about 'whether' but – even better – about 'how much,' because it is an anthropological necessity to adapt and shape existing nature to human needs. For example, the philosopher Klaus Michael Meyer-Abich sees the situation as follows: " … we humans are not there to leave the world as though we had never been there. As with all other life forms, it is also part of our nature and our lives to bring about changes in the world. Of course, this does not legitimize the destructive ways of life that we have fallen into. But only when we basically approve of the changes in the world can we turn to the decisive question of which changes are appropriate for human existence and which are not" (Meyer-Abich, 1996).

It is therefore unavoidable to make a sensible judgment of the balance between necessary interventions into the environment and the risks posed by these interventions to human health and environmental quality. However, at the same time, it must be kept in mind that these interventions often inflict irreversible damage on the environment and destroy possible future-usage potentials for future generations. Above and beyond this, for the human race, nature is a cradle of social, cultural, aesthetic, and religious values, the infringement of which, in turn, has a major influence on people's well-being (Pidgeon et al., 2010: 95). On both sides of the equation, there are therefore important goods that have to be appreciated when interventions in nature occur. But what form should such an appreciation take?

If the pros and cons of the intervention in nature have to be weighed against each other, criteria are needed that can be used as yardsticks. Who can and may draw up such criteria, according to which standards should the interventions be assessed and how can the various evaluative options for action be compared with each other for each criterion?

Taking risks always involves two major components: an assessment of what we can expect from an intervention into the environment (be it the use of resources or the use of environments as a sink for our waste). This is the risk- and benefit-assessment side of the risk analysis. Next, we need to decide whether the assessed consequences are culturally or socially desirable. While the estimate of consequences broadly falls in the domain of scientific research and expertise, with uncertainties and ambiguities in particular having to be taken into account (IRGC, 2005; Renn et al., 2011), the question about the foundations for evaluating various options for action and about drawing up standards guiding action is a central function of ethics (Taylor, 1986). Both components, the assessment and the evaluation part of risk analysis will be explained in more detail in the sections below.

Generic Principles for Human Interventions into the Environment

Since contemporary society and the generations to come certainly use, or will use, natural resources, the question of legitimizing interventions into the natural environment is

mainly a question of how much of what nature needs to be conserved and what can be used for human purposes. Nature itself cannot show society what it is essential to conserve and how much nature can be traded for valuable commodities. Humans alone are responsible for a decision and the resulting conflicts between competing objectives. Appreciation and negotiation processes are therefore the core of the considerations about the ethical justification of rules for interventions. In this debate about the acceptability of environmental risk, it is advisable to make a distinction between inviolate principles and criteria, which allow trade-offs between them (Darwall, 2014: 14). Let us start with the principles: It follows on from the basic principle of conserving human life that all human interventions that threaten the ability of the human race as a whole, or a significant number of individuals alive today or in the future, to exist should be categorically prohibited. This refers to intervention threats to the systemic functions of the biosphere. Such threats are one of the guiding principles that must not be exceeded under any circumstances, even if this excess were to be associated with high benefits. In the language of ethics, this is a categorical principle; in the language of economics, a good that is not capable of being traded (Moldan et al., 2012: 7f.). The set of categorical prohibitions should, however, be used very sparingly because plausible trade-offs can be thought up for most principles, the partial exceeding of which appears intuitively. In the case of threats to existence, however, the categorical rejection of the behavior that leads to this is obvious.

But what does the adoption of categorical principles specifically mean for the political molding of environmental protection? In the past, a number of authors have tried to specify the minimum requirements for an ethically responsible moral system with respect to biosphere use. These so-called 'safe minimum standards' specify thresholds for the open-ended measurement scale of the consequences of human interventions that may not be exceeded even if there is a prospect of great benefits (Randall, 1988; Randall and Farmer, 1995). In order to be able to specify these thresholds in more detail, the breakdown into three levels proposed by the German Scientific Council for Global Environmental Change is helpful (WBGU, 2000: 325f.). These levels are:

- the global bio–geochemical cycles in which the biosphere is involved as one of the causes, modulator, or 'beneficiary';
- the diversity of ecosystems and landscapes that have key functions as bearers of diversity in the biosphere; and
- the genetic diversity and the species diversity that are both 'the modeling clay of evolution' and basic elements of ecosystem functions and dynamics.

When the first level is concerned, in which the functioning of the global ecosystem is at stake, categorical principles are obviously necessary and sensible, provided that no one wants to shake the primary principle of the permanent preservation of the human race. *Accordingly, all interventions in which important substance or energy cycles are significantly influenced at a global level and where globally effective negative impacts are to be expected are categorically prohibited*. Usually, no stringently causal evidence of the harmful nature of globally relevant information is needed; justified suspicion of such harmfulness should suffice.

On the second level, the protection of ecosystems and landscapes, it is much more difficult to draw up categorical rules. Initially, it is obvious that all interventions in landscapes in which the global functions mentioned on the first level are endangered must be avoided. Above and beyond this, it is wise from a precautionary point of view to maintain as much ecosystem diversity as possible in order to keep the degree of vulnerability to the unforeseen or even unforeseeable consequences of anthropogenic and nonanthropogenic interventions as low as possible. Even though it is difficult to derive findings for human behavior from observations of evolution, the empirically proven statement "he who places everything on one card, always loses in the long run" seems to demonstrate a universally valid insight into the functioning of systemically organized interactions (Renn, 2014: 502ff.). For this reason, the conservation of the natural diversity of ecosystems and landscape forms is a categorical principle, whereas the depth of intervention allowed should be specified on the basis of principles and standards capable of compensation.

The same can be said for the third level, genetic and species protection. Here too, initially the causal chain should be laid down: species conservation, landscape conservation, maintaining global functions. Wherever this chain is unbroken, a categorical order of conservation should apply. These species could be termed *primary key species*. This includes such species that are not only essential for the specific landscape type in which they occur, but also for the global cycles above and beyond this specific landscape type – thanks to their special position in the ecosystem. Probably, it will not be possible to organize all species under this functional contribution to the surrounding ecosystem, but we could also think of groups of species, for example, humus-forming bacteria. In second place, there are the species that characterize certain ecosystems or landscapes. Here they are referred to as *secondary key species*. They, too, are under special protection that is not necessarily under categorical reservations. Their function value, however, is worthy of special attention. Below these two types of species, there are the remaining species that perform ecosystem functions to a greater or lesser extent. Generally, here, too, as with the issue of ecosystem and landscape protection, the conservation of diversity as a strategy of 'reinsurance' against ignorance, global risks, and unforeseeable surprises is recommended (WBGU, 1999).

It remains to be said that from a systemic point of view, a categorical ban has to apply to all human interventions where global closed loops are demonstrably at risk. Above and beyond this, it makes sense to recognize the conservation of landscape variety (also of ecosystem diversity within landscapes) and of genetic variety and species diversity as basic principles, without being able to make categorical judgments about individual landscape or species types as a result.

Compensatory Principles and Standards

In order to evaluate partial infringements of compensatory principles or standards, which are referred to in the issue of environmental protection, we need rules for decision-making that facilitate the balancing process necessary to resolve compensatory conflicts. In the current debate about rules for

using the environment and nature, it is mainly teleological valuation methods that are proposed (Ott, 1993).

These methods are aimed at:

- estimating the possible consequences of various options for action at all dimensions relevant to potentially affected people,
- recording the infringements or fulfillments of these expected consequences in the light of the guiding standards and principles, and then
- aggregating them according to an internal key so that they can be weighed up in a balanced way.

On the positive side of the equation, there are the economic benefits of an intervention and the cultural values created by use, for example, in the form of income, subsistence (self-sufficiency), or an aesthetically attractive landscape (parks, ornamental gardens, etc.); on the negative side, there are the destruction of current- or future-usage potentials, the loss of unknown natural resources that may be needed in the future, and the violation of aesthetic, cultural, or religious attributes associated with the environment and nature.

There are, therefore, related categories on both sides of the equation: current versus possible uses in the future, development potentials of current uses versus option values for future use, shaping the environment by use versus impairments to the environment as a result of alternative use, etc. With the same or similar categories on the credit and debit side of the balance sheet, the decision is easy when there is one option that performs better or worse than all the other options for all categories. Although such a *dominant* (the best for all categories) or *subdominant option* (the worst for all categories) is rare in reality, there are examples of dominant or subdominant solutions.

Thus, for example, the overfelling of the forests of Kalimantan on the island of Borneo in Indonesia can be classed as a subdominant option, since the short-term benefit, even with extremely high discount rates, is in no proportion to the long-term losses of benefits associated with a barren area covered in *Imperata* grass. The recultivation of a barren area of this kind requires sums many times the income from the sale of the wood, including interest. Apparently there are no cultural, aesthetic, or religious reasons for conversion of primary or secondary woodland into grassland. This means that the option of deforestation should be classed as of less value than alternative options for all criteria, including economic and social criteria (Radandt et al., 2008: 231).

But if we disregard the dominant or subdominant solutions, an appreciation between options that violate or fulfill compensatory standards and principles depends on two preconditions: best possible knowledge of the consequences (what happens if I choose option A instead of option B?) and a transparent, consistent rationale for weighing up these consequences as part of a legitimate political decision process (are the foreseeable consequences of option A more desirable or bearable than the consequences of option B?) (Gregory et al., 2012: 17).

Knowledge

Adequate knowledge of the consequences is needed in order to reveal the systemic connections between resource use, ecosystem reactions to human interventions, and sociocultural context (Becker, 1999: 286). This requires interdisciplinary and transdisciplinary research and cooperation. The task of applied ecological research, for example, is to show the consequences of human intervention in the natural environment and how ecosystems are burdened by different interventions and practices. The economic approach provides a benefit-oriented valuation of natural and artificial resources within the context of production and consumption, as well as a valuation of transformation processes according to the criterion of efficiency. Cultural and social sciences examine the feedback effects between use, social development, and cultural self-perception. They illustrate the dynamic interactions between usage forms, sociocultural lifestyles, and control forms.

Interdisciplinary, problem-oriented, and system-related research contribute jointly to forming a basic stock of findings and insights about functional links in the relationship between human interventions and the environment, and also in developing constructive proposals as to how the basic question of an ethically justified use of the natural environment can be answered in agreement with the actors concerned.

Accordingly, in order to ensure sufficient environmental protection, scientific research, but especially transdisciplinary system research at the interface between natural sciences and social sciences is essential. Bringing together the results of interdisciplinary research, the policy-relevant choice of knowledge banks and balanced interpretation in an environment of complexity, uncertainty, and ambiguity are difficult tasks that primarily have to be performed by the science system itself (Klinke and Renn, 2012).

Valuation of Consequences

But knowledge alone does not suffice. In order to be able to act effectively and efficiently while observing ethical principles, it is necessary to shape the *appreciation process* between the various options for action *according to evaluative criteria* (Gowdy, 1999: 172ff.). To do this, first of all, it is necessary to identify the dimensions that should be used for a valuation. The discussion about the value dimensions to be used as a basis for valuation is one of the most popular subjects within environmental ethics. To apply these criteria in risk evaluation and to combine the knowledge aspects about expected consequences of different behavioral options with the ethical principles is the task of what we have called the risk governance (Renn, 2008: 47ff.).

The following section will present a risk governance framework for applying these principles into environmental policy making under risk. The main line of argument is that risk management requires an analytic-deliberative approach for dealing effectively and prudently with environmental risks.

A Risk Governance Approach to Environmental Risk Taking

Assessing potential consequences of human interventions and evaluating their desirability on the basis of subsequent knowledge and transparent valuation criteria are two of the central tasks of the risk governance process. Risk governance

deals with the identification, assessment, management, evaluation, and communication of risks in the context of plural values and distributed authority. It includes the totality of actors, rules, conventions, processes, and mechanisms and is concerned with how relevant risk information is collected, analyzed, and communicated, and how management decisions are taken (IRGC, 2005). Risk governance is both a descriptive (how are decisions made) as well as normative concept (how should decisions be made). In its application as a normative concept, it specifies the principles of good governance that include transparency, effectiveness and efficiency, accountability, strategic focus, sustainability, equity and fairness, respect for the rule of law, and the need for the chosen solution to be politically and legally feasible as well as ethically and publicly acceptable.

For dealing with complex environmental risks, the governance structure requires a set of resources associated with the prudent handling of complexity, uncertainty, and ambiguity. In 2005, the International Risk Governance Council (IRGC) suggested a process model for risk governance (IRGC, 2005; Klinke and Renn, 2012; Renn and Walker, 2008). This framework structures the risk governance process in four phases: pre-assessment, appraisal, characterization and evaluation, and risk management. Communication and stakeholder involvement were conceptualized as constant companions to all four phases of the risk governance cycle. Based on this framework and informed by many comments on the original framework, Klinke and Renn modified the original IRGC proposal (Klinke and Renn, 2012). The new framework consists of the steps: pre-estimation, interdisciplinary risk estimation, risk characterization, risk evaluation, and risk management. This is all related to the ability and capacity of risk governance institutions to use resources effectively (see **Figure 1**).

Appropriate resources include institutional and financial means as well as social capital (e.g., strong institutional mechanisms and configurations, transparent decision-making, allocation of decision-making authority, formal and informal networks that promote collective risk handling, education), technical resources (e.g., databases, computer soft- and hardware, etc.), and human resources (e.g., skills, knowledge, expertise, epistemic communities, etc.). Hence the adequate involvement of experts, stakeholders, and the public in the risk governance process is a crucial dimension to produce and convey adaptive and integrative capacity in risk governance institutions (Pelling et al., 2008).

Therefore, the plural values of a heterogeneous expert, stakeholder, and public preferences have to be incorporated in the risk governance process. But how can this be done given the wealth of competing values and preferences? Should we simply accept the results of opinion polls as the basis for making political decisions? Can we rely on risk perception results to judge the seriousness of pending risks? Or should we place all our faith in professional risk management?

If we turn to professional help to deal with plural-value input, economic theory might provide us an answer to this problem: If environmental goods are made individual and suitable for the market by means of property rights, the price that forms on the market ensures an appropriate valuation of the environmental good (Burgmann, 2005). Every user of this good can then weigh up whether he is willing to pay the price or would rather not use the good. With many environmental goods, however, this valuation has to be made by collective action, because the environmental good concerned is a collective or open access good. In this case, a process is needed that safeguards the valuation and justifies it to the collective. However, this valuation cannot be determined with the help of

Figure 1 Adaptive and integrative risk governance model. Adapted from Klinke, A., Renn, O., 2012. Adaptive and integrative governance on risk and uncertainty. Journal of Risk Research 15 (3), 273–292.

survey results. Although surveys are needed to be able to estimate the breadth of preferences and people's willingness to pay, they are insufficient for a derivation of concrete decision-making criteria and yardsticks for evaluating the tolerability of risks to human health and the environment (Radandt et al., 2008: 235).

- First, the individual values are so widely scattered that there is little sense in finding an average value here.
- Second, the preferences expressed in surveys change much within a short time, whereas ethical valuations have to be valid for a long time.
- Third, preferences are frequently based on flawed knowledge or ad hoc assumptions both of which should not be decisive according to rational considerations.

What is needed, therefore, is a gradual process of assigning trade-offs in which existing empirical values are put into a coherent and logically consistent form. A report by the American Academy of Sciences on the subject of 'Understanding environmental risks' (US-National Research Council, 1996, 2008) comes to the conclusion that scientifically valid and ethically justified procedure for the collective valuation of options for risk handling can only be realized within the context of – what the authors coin – an analytic-deliberative process. *Analytic* means that the best scientific findings about the possible consequences and conditions of collective action are incorporated in the negotiations; *deliberative* means that rationally and ethically transparent criteria for making trade-offs are used and documented externally. Moreover, the authors consider that fair participation by all groups concerned is necessary to ensure that the different moral systems that can legitimately exist alongside each other should also be incorporated in the process.

A combination of analytic and deliberative processes can help explore the space of judgments and evaluations relating to complexity, uncertainty, and ambiguity (Renn, 2008: 284ff.). Most environmental agencies go through an environmental assessment process and provide opportunities for public review and comment. Many controversial environmental decisions become the focus of large analytical efforts, in which mathematical models are used to predict the environmental, economic, and health consequences of environmental management alternatives. Analysis should be seen as an indispensable complement to deliberative processes, regardless whether this analysis is sophisticated or not. Even simple questions need analytic input for making prudent decisions, especially in situations where there is controversy about the legitimacy of the human intervention into the environment.

Beyond the analytic input, the process of risk evaluation requires deliberation among and between different stakeholders. This second component 'deliberation' is even more difficult to put into practice than dealing with plural assessment results (Gregory et al., 2012: 24f.). Deliberation requires to (Webler, 1995):

- seek a consensus on the procedure that all participants want to employ in order to derive the final decision or compromise, such as voting, sorting of positions, consensual decision-making, or the involvement of a mediator or arbitrator;
- articulate and criticize factual claims on the basis of the 'state of the art' of scientific knowledge and other forms of problem-adequate knowledge (in the case of dissent, all relevant camps have the right to be represented);
- interpret factual evidence in accordance with the laws of formal logic and analytical reasoning;
- disclose their relevant values and preferences, thus avoiding hidden agendas and strategic game playing;
- process data, arguments, and evaluations in a structured format (e.g., a decision-analytic procedure) so that norms of procedural rationality are met and transparency can be created.

What needs to be deliberated? First, deliberative processes are needed to define the role and relevance of systematic and anecdotal knowledge for making far-reaching choices. Second, deliberation is needed to find the most appropriate way to deal with uncertainty in environmental decision-making and to set efficient and fair trade-offs between potential over- and underprotection. Third, deliberation needs to address the wider concerns of the affected groups and the public at large.

Why can one expect that deliberative processes are better suited to deal with environmental challenges than using expert judgment, political majority votes, or relying on public survey data (Renn, 2008: 306ff.)?

- Deliberation can produce common understanding of the issues or the problems based on the joint-learning experience of the participants with respect to systematic and anecdotal knowledge.
- Deliberation can produce a common understanding of each party's position and argumentation and thus assist in a mental reconstruction of each actor's argumentation. The main driver for gaining mutual understanding is empathy. The theory of communicative action provides further insights in how to mobilize empathy and how to use the mechanisms of empathy and normative reasoning to explore and generate common moral grounds (Webler, 1995).
- Deliberation can produce new options and novel solutions to a problem. This creative process can either be mobilized by finding win–win solutions or by discovering identical moral grounds on which new options can grow.
- Deliberation has the potential to show and document the full scope of ambiguity associated with environmental problems. Deliberation helps to make a society aware of the options, interpretations, and potential actions that are connected with the issue under investigation (Wynne, 1992). Each position within a deliberative discourse can only survive the crossfire of arguments and counterarguments, if it demonstrates internal consistency, compatibility with the legitimate range of knowledge claims, and correspondence with the widely accepted norms and values of society. Deliberation clarifies the problem, makes people aware of framing effects, and determines the limits of what could be called reasonable within the plurality of interpretations.
- Deliberations can also produce agreements. The minimal agreement may be a consensus about dissent. If all arguments are exchanged, participants know why they disagree.

They may not be convinced that the arguments of the other side are true or morally strong enough to change their own position; but they understand the reasons why the opponents came to their conclusion. In the end, the deliberative process produces several consistent and – in their own domain – optimized positions that can be offered as package options to legal decision-makers or the public. Once these options have been subjected to public discourse and debate, political bodies, such as agencies or parliaments can make the final selection in accordance with the legitimate rules and institutional arrangements such as majority vote or executive order. Final selections could also be performed by popular vote or referendum.

- Deliberation may result in consensus. Often deliberative processes are used synonymously with consensus-seeking activities (Coglianese, 1997). This is a major misunderstanding. Consensus is a possible outcome of deliberation, but not a mandatory requirement. If all participants find a new option that they all value more than the one that they preferred when entering the deliberation, a 'true' consensus is reached (Radandt et al., 2008: 245). It is clear that finding such a consensus is the exception rather than the rule. Consensus is either based on a win–win solution or a solution that serves the 'common good' and each participant's interests and values better than any other solution. Less stringent is the requirement of a tolerated consensus. Such a consensus rests on the recognition that the selected decision option might serve the 'common good' best, but on the expense of some interest violations or additional costs. In a tolerated consensus, some participants voluntarily accept personal or group-specific losses in exchange for providing benefits to all of society.

In summary, many desirable products and accomplishments are associated with deliberation (Chess et al., 1998). Depending on the structure of the discourse and the underlying rationale, deliberative processes can:

- enhance understanding;
- generate new options;
- decrease hostility and aggressive attitudes among the participants;
- explore new problem framing;
- enlighten legal policy-makers;
- produce competent, fair, and optimized solution packages; and
- facilitate consensus, tolerated consensus, and compromise.

In a situation of major value conflicts, the deliberation process may involve soliciting a diverse set of viewpoints, and judgments need to be made on what sources of information are viewed as responsible and reliable. Publication in scientific journals and peer review from scientists outside the government agency are the two most popular methods by which managers or organizers of deliberative processes try to limit what will be considered as acceptable evidence. Other methods are to reach a consensus among the participants up front, which expertise should be included in the deliberation or to appoint representatives of opposing science camps to explain their differences in public.

Conclusions

The objective of this article was to address and characterize the main components of assessing, evaluating, and managing environmental risks. Effective environmental risk governance needs a structure that assures the integration of technical expertise, regulatory requirements, and public values. These different inputs should be combined in such a fashion that they contribute to the best knowledge available in the field and to the plurality of values that govern the judgment of desirability for oneself and society as a whole. It does not make sense to replace technical expertise with vague public perceptions, nor is it justified to have the experts insert their own value judgments into what ought to be a democratic process.

An analytic-deliberative model of risk governance can provide assistance in problem structuring, in dealing with complex scientific issues and uncertainty, and in helping society to understand disagreements and ambiguity with respect to values and preferences. For supporting such an analytic-deliberative process, the IRGC risk framework can be used for environmental assessment and risk handling. It is designed to explore difficult issues, to focus debate and further analysis on the factors most important to the decision, and to provide for increased transparency and more effective exchange of information and opinions among the process participants.

The full power of the analytic-deliberative approach to risk governance lies in the combination of risk assessment through analytic methods and risk evaluation and management through deliberative procedures. Experienced analysts may be needed to guide the implementation of the analytical tools for aiding decisions. Skilled communicators and facilitators may be needed to design and conduct the deliberative processes as a means to provide a fair and comprehensive representation of societal values and preferences. Integrating analysis and deliberation can help to generate and sustain transparency and trust.

Abstract

The environmental sciences are engaged in a remarkable effort of interdisciplinary cooperation and integration. Some long-running international scientific programs, notably the World Climate Research Programme and the International Geosphere-Biosphere Programme, play an important role therein. The origin of the environmental sciences is discussed, in particular physical geography and meteorology in the work of Alexander von Humboldt. The development of ecology during the nineteenth and twentieth centuries is traced through the work of Charles Darwin, and its historical bifurcation in evolutionary and systems approaches. The current focus on data is examined on the basis of the Long Term Ecological Research Network, and its precursor, the Grassland Biome study in the United States, 1968–76. The history of meteorology is discussed from the work of Vilhelm Bjerkness in Sweden to the development of the General Circulation Models, which form the basis of present studies of global warming and the 'human fingerprint.' Climate skepticism and geoengineering form two extreme but widely discussed attitudes toward global warming, in society and academia.

Introduction

The environmental sciences, meteorology, physical geography, ecology, and urban and regional planning are engaged in a remarkable effort of interdisciplinary cooperation and integration. The importance of climate change (and the related issue of biodiversity loss) is one driver of this process. The rise of the average global temperature will cause all kinds of interacting physical, biological, and social changes and they need to be addressed interdependently. Another driver is the political climate in which public expenditure on science is under pressure. The environmental sciences need to prove their continuing relevance for the public agenda and to show that they spend public funds wisely and efficiently. Orchestrating interdisciplinary integration of the environmental sciences is some worldwide research programs on the Earth system, under the auspices of the International Council for Science (ICSU). The World Climate Research Programme (WCRP) has been running since 1980, and the International Geosphere-Biosphere Programme (IGBP) became operational in 1988. At their start, the WCRP housed meteorology and other physical sciences, while the IGBP had ecology, atmospheric chemistry, and other biological, geological, and chemical sciences. Within the programs themselves, all kinds of disciplinary delineations were clearly visible. In recent decades, a remarkable effort in top-down planning has wiped away many of the dividing lines between disciplines, and it is expected that the WCRP and the IGBP will merge in the near future. The scientific results of the programs are increasingly evaluated on the basis of their proven relevance for climate assessments by the Intergovernmental Panel on Climate Change (IPCC) (ICSU/IGFA, 2009). There is also an increasing coordination with programs that investigate biodiversity (DIVERSITAS) and the social consequences of climatic change, the International Human Dimensions Programme. These programs also have ICSU as their sponsor. It is important to note that the ICSU is a body that speaks in the name of 'science,' not governments, while the scientists participating in the programs usually are university scientists and have a background in what used to be called 'fundamental science.' Insofar as the WCRP and the other programs do have a link with the world of policy, it is primarily through national funding agencies, such as the National Science Foundation in the United States, which have backgrounds in 'pure' science. However, increasingly, such programs have taken up socially oriented goals. The combined efforts of the program organizations and the funding agencies influence the 'little science' work modes at universities worldwide (Kwa, 2006).

Ecology

The Beginnings of Environmental Science in the Nineteenth Century

At the start of the twenty-first century, the environmental sciences, by achieving a fairly high degree of integration across disciplinary boundaries, have come full circle. Before the disciplines established themselves in the second half of the nineteenth century, several of them originated together through the work of just one individual, Alexander von Humboldt (1769–1859). Humboldt had received a university education in geology. When he was an Inspector of Mines, the inheritance of his family fortune enabled him to give up his position and to embark on a career in the service of the Prussian government. By then, he had been in contact with the naturalists on board Captain James Cook's scientific expeditions in the Pacific. In 1798, Humboldt began his own journey to Latin America. He climbed Mt Chimborazo, at the time considered the world's highest mountain. Upon his return in 1804, he became the most famous man in Europe after Napoleon. An important conceptual innovation of Alexander von Humboldt was the transformation of 'landscape' into a subject matter for science. Previously, the word landscape referred to a particular genre in painting, and Humboldt made good use of the painterly gaze, which confers unity on what it sees. Humboldt thus grasped a particular landscape, in effect, as an individual being, with a distinct 'physiognomy,' i.e., with its own visual characteristics and beauty (Kwa, 2005).

Foremost in the appearance of a landscape was its *vegetation*, another new concept, since it grouped plants according to the place where they lived rather than following their taxonomical order. Humboldt discovered that very different species occurred together, and that there were social relations among them, and he called these groupings plant associations.

The first modern textbook on ecology by the Danish botanist Eugenius Warming appeared in 1895, with the English translation appearing in 1909. Warming retained Humboldt's original precepts on plants in social associations, and worked them out in a precise manner, exposing the diversity of degrees and styles of interdependence that were found in nature. Josias Braun-Blanquet in Montpellier pursued this line of thought, and he and others in the so-called Zürich-Montpellier school produced a comprehensive system of Europe's plant associations. This vegetation science would play a major role in underpinning ecological support for nature conservation practices in many countries of continental Europe (Nicolson, 1989).

Darwin and Evolutionary Ecology

Charles Darwin's famous *Origin of Species*, first published in 1859, is as much a treatise on ecology as it is on evolutionary theory. Darwin owed much to Humboldt's holistic ecology, as he saw the various species of animals and plants forming an 'entangled' whole. But whereas Humboldt stressed harmony in nature, Darwin regarded nature much more as a creative force. Nature continually disturbs settled equilibria through the struggle of species scrambling for existence (Worster, 1985).

Darwin's work remained close to taxonomical practice in zoology and botany. He had worked for 8 years on the barnacle alone before publishing the *Origin of Species*, and he was in lifelong correspondence with Joseph Hooker, the leading taxonomist of his day, exchanging more than 1300 letters (Endersby, 2008). Hooker was the Director of the Royal Botanical Gardens at Kew, the center of an imperial network of collectors of plant species around the globe. The New York Botanical Garden was founded in 1891, just when ecology was developing into a field of study in the United States. The garden helped to facilitate the early development of ecology by providing training and research facilities (Kingsland, 2005). Although institutions devoted to taxonomy declined in importance during much of the twentieth century, the issue of biodiversity provided them with a new mission (Escobar and Paulson, 2005; Takacs, 1996).

Evolutionary ecologists stress interactions between species (populations). They do not regard the climate as the determinate factor in the makeup of animal communities, as ecosystem ecologists tend to do. Population dynamics has strong ties with applied ecology, including economic entomology (the study of pest insects in agriculture) and fishery ecology. Already by 1900, ecologists were working on biological pest control, i.e., the method of holding one insect species in check with another one. The publication of Rachel Carson's *Silent Spring* gave this research a boost (Perkins, 1982; Palladino, 1993).

Several approaches in population dynamics, in particular those of Robert May and C.S. Holling, have enlarged its theoretical basis in diverse ways. Both developed new mathematical techniques, which tackled the occurrence of more or less dramatic changes in ecological systems. In the work of Daniel Botkin, an evolutionary ecological approach is focusing on unique events in order to solve problems of nature conservation in local contexts, in contrast to the more general outlook of systems ecology. An evolutionary ecological style of work also is informing field experiments in ecology. Field experiments, such as the ongoing restoration of Lake Sempach in Switzerland, do not aim at controlling an environment, as in a laboratory experiment, but instead are oriented toward contingency (Schwartz and Krohn, 2011).

Ecosystems and Systems Ecology

Systems ecology is the mathematical, computer-implemented form of ecosystem ecology. The latter assumes that large entities such as landscapes are functionally integrated wholes and it attempts to uncover their structure and functioning.

The word 'ecosystem' was coined in 1935 by Arthur Tansley, a British ecologist. Tansley wanted to place the older associationist or community-oriented ecology on a mechanistic footing. This idea remained largely programmatic until the 1950s, when Eugene Odum pulled together some theoretical approaches and physical methodologies. Odum's synthesis launched ecosystem ecology. It incorporated an emphasis on 'productivity,' which was added to the analysis of food web relations first pioneered by Charles Elton in the United Kingdom. Odum made use of newly available physical methodologies, most importantly radioactive tracers. His approach was based on a recent discovery that several species accumulate radioactive isotopes, as they picked them up in minute quantities from the environment. Radioactive tracers permitted the elucidation of food webs both qualitatively (who eats what) and quantitatively. Odum also put the food web relations through a process of abstraction and conceived them as the circulation of matter and energy in the ecosystem. Through computer simulation of ecosystem models Odum's fellow ecosystem ecologists hoped to find the key to the rational exploitation and control of natural resources. They hoped to use the models to help them establish the conditions under which ecosystems preserve their stability and to identify the natural mechanisms that enable them to do so.

From 1968 to 1976, five very large systems ecology programs were implemented in the United States in the so-called biome studies of the International Biological Program (IBP), comprising large parts of the North American continent. The largest of these was the Grassland Biome Study at the Colorado State University. This project was headed by George Van Dyne, who by 1969 was principal investigator for 130 scientists and whose charismatic leadership went through a major crisis. These studies were pioneering in two ways: they embarked on large-scale data collection and they built computer models in an effort to simulate the entire biome. For collecting data, the Grassland Biome Study built a network; for instance, ecologists at a dozen land grant schools were contracted to clip and weigh grass at allotted pieces of land, in order to measure grass productivity. At the termination of the IBP, the comprehensive model was judged in the scientific community as both too overloaded with variables and too crude and static (Kwa, 1993; Aronova et al., 2010). Yet, ecological modeling was proven feasible, and this was true as well for the equally crude large-scale data gathering. When the National Science Foundation (NSF), in 1980, created the Long

Term Ecological Research Network (LTER), several former IBP sites were included (Kingsland, 2005; Coleman, 2010).

An outstanding feature of research at the LTER sites is the care devoted to storing data and making them available to the other sites and to researchers internationally. NSF's proactive data policy resulted in the designation of Network Data Managers centrally and for each of the sites. Metadata, the description of the data, become standardized and data are organized following 'ontologies,' a hierarchical form of data ordering developed in information science. However, several aspects of data management and data integration remain contested among scientists and difficult to implement (Baker and Bowker, 2007; Bowker, 2000).

Meteorology

Humboldt had invented isotherms, lines on a map that connect points with equal mean temperature. Together with isobars and a number of other graphic representations, such as of storm tracks, isotherms formed the basis of weather forecasting well into the twentieth century. The continuity suggested by the lines invited a hunt after ever more data, which no table with only 'point data' could have achieved (Edwards, 2010). But the skillful combination of various forms of data involved many rules of thumb.

Vilhelm Bjerknes and the Bergen School of Meteorology

Modern meteorology was founded by Vilhelm Bjerknes and his 'Bergen school' in Norway. He visualized the atmosphere as consisting of three-dimensional air masses moving around the globe, varying in temperature, density, and humidity. An important step was achieved by Bjerknes' son Jacob, who developed a model of the extratropical cyclone and how it moves. Bjerknes was able to exploit an existing military observational network for weather forecasting in western Norway, which enabled him to follow the movement of the cyclones. The model also brought him considerable popular support in the area. The major breakthrough occurred in 1919, when the concept of the 'polar front' was born. It would take several decades before the world's meteorologists were persuaded to 'see' a battle line, separating cold air masses from the north and warm air masses from the south. Bjerknes thought that this line stretched along the entire Atlantic, or indeed around the entire globe. Along the polar front, the cyclones, or low-pressure areas, were formed, which would hit the coasts of Europe with rain and storm. Bjerknes placed weather forecasting on a new footing, as the analysis of polar fronts for the purpose of forecasting relied on large networks for atmospheric data gathering (Friedman, 1989; Edwards, 2010).

The Bergen school's ideas received a decisive boost when Carl-Gustaf Rossby (1898–1967), a Swede who had worked with Bjerknes in Bergen, came to work at the US Weather Bureau during 1926–27. In the late 1930s, Rossby, by then at Massachusetts Institute of Technology, developed a method for calculating large-scale motion in the atmosphere, based on the movement of long waves (later to be called Rossby waves). He put the westward movement of the extratropical cyclones more rigorously into the context of the general circulation of the Earth's atmosphere, thus explaining semiquantitatively how the cyclones moved. On the basis of Rossby's work, precision in forecasting methods was greatly enhanced in succeeding years.

Numerical Prediction of the Weather with the Computer

John von Neumann, a mathematician, was one of the main architects of the modern computer. During World War II, he had been working on the atom bomb at Los Alamos. After the war, he initiated a project to build an 'all-purpose, automatic, high-speed electronic computing machine.' von Neumann also formulated the problems that computers were to solve, among them the modeling of the atmosphere. The reason why von Neumann chose meteorology may have been the military importance of weather forecasts. Jule Charney became von Neumann's collaborator in 1948. In early April 1950, the first successful numerical weather prediction was completed, on the basis of Charney's simple two-dimensional model of the atmosphere. Routine numerical weather prediction began by 1955.

The early models by Charney derived intellectually from the Bergen school. In the mid-1960s, however, these models were replaced in daily forecasting by models based on the so-called primitive equations, basic physical equations describing the atmosphere. As a result, the original Bergen 'fronts' moved to the background in numerical meteorology (Nebeker, 1995).

General Circulation Models

The US Weather Bureau created a General Circulation Research Section in 1955, renamed the Geophysical Fluid Dynamics Laboratory in 1963. General Circulation Models (GCMs) were to simulate the circulation of the Earth's entire atmosphere. Joseph Smagorinsky, its first Director, did not go for quick results. Instead, he believed that physical theory and numerical methods should be developed and corrected first, before any verisimilitude in the behavior of the empirically measured atmosphere could be established. During the 1960s, two more GCMs were developed, at the Lawrence Livermore National Laboratory and at the National Center for Atmospheric Research. These three models were the first of all the GCMs now in operation, estimated to be 18 if one counts only the models that link the atmosphere to the circulation of the oceans. There has been exchange of computer code between the models, and the models also are often compared with each other, leading to theoretical convergence. A related but different process is that the models are constantly being fine-tuned against all the known historical data sets of climatic variables. This is a two-way process, since the data are themselves constantly being recalibrated and reinterpreted according to modeling requirements. One obvious reason is that data sets were obtained through different measurement protocols and with different equipment. 'Raw data,' therefore, do not exist (Edwards, 2010).

Climate Skepticism

Global warming as a policy issue made its breakthrough in 1988, when James Hansen, the Director of the Goddard Institute for Space Studies, delivered a famous testimony before a Committee of the American Congress. Presidential Candidate George H. Bush promised 'to counter the Greenhouse effect by the White House effect.' A year later, physicist

William Nierenberg requested and received permission to present at the White House an unpublished report of the George C. Marshall Foundation (of which he was a cofounder), in which naturally fluctuating sun spots were identified as the sole cause of global warming and the link between global warming and human use of fossil fuels was denied (Oreskes and Conway, 2010). From then on, and in marked contrast with the European Union, the US government would refrain from policies to bring down carbon dioxide emissions in the atmosphere.

Frederick Seitz, another cofounder of the Marshall Institute, in a first-page article of the *Wall Street Journal* in 1996, accused the IPCC of fraud. The immediate target was a study by climate scientist Ben Santer, published in the IPCC's *Second Assessment Report* (1995). Santer had identified a 'human fingerprint' in the warming of the atmosphere, a particular aspect that could not be explained by the sun's activity but which could be explained by the raised level of carbon dioxide in the atmosphere. According to Seitz, the IPCC had not followed its own rules of peer-reviewed check before publishing Santer's study. The IPCC had in fact conducted such a check, although it has since sharpened its procedures. Santer's finding still stands, although at the time the damage to the IPCC and Santer personally was considerable.

From an overview of the interventions in the policy arena by Nierenberg, Seitz, and some fellow 'climate skeptics' such as Fred Singer, it has been found that their denial of a human influence on global warming is connected with a broader agenda. Enjoying considerable influence as elder statesmen of science, they have also made their mark by casting doubt on the deleterious effects of acid rain and the damaging effects of chlorofluorocarbons on the ozone layer, and they also denied the effects on health of passive smoking. The common denominator is that they opposed all governmental environmental regulation, in line with economic interests that oppose such regulations as antibusiness (Lahsen, 2005; Oreskes and Conway, 2010).

Nierenberg and Seitz were elite scientists, but in the cause of climate skepticism they were joined by a number of activists and citizen scientists. Steven McIntyre, a retired Canadian businessman, with an educational background in mathematics and economics, in 2005 launched 'Climate Audit,' a blog that scrutinizes climate data. McIntyre in particular attacked the validity of the reconstruction of the Earth's temperature over the last 1000 years by climatologist Michael Mann. Called 'the hockey stick graph,' the graphic reconstruction shows a steady but slow decline in temperature until 1900, and a steep rise thereafter. The controversy was long and bitter, and drew in many parties, including the US National Academy of Sciences and the US Congress. To date, the hockey stick has been confirmed by a number of subsequent temperature reconstructions (Edwards, 2010).

Geoengineering

A recent report issued by the UK Royal Society (2009) on geoengineering stands on the opposite end of the spectrum of scientific and societal reactions to the danger of global warming from that of the climate skeptics. Geoengineering as currently understood comprises two basic techniques for intervening in the global physics of the atmosphere: 'solar radiation management' and 'carbon dioxide capture.' The most serious method of solar radiation management is blasting aerosols in the atmosphere, in order to achieve a cooling effect similar to large volcanic eruptions. An example of carbon capture is fertilizing the ocean with iron, which would cause algal bloom and thereby capture carbon dioxide from the atmosphere. The Royal Society report asks "Why should appropriate geoengineering options not be added to the portfolio of options of dealing with climate change?" (Royal Society, 2009: p. 45). The report adds that "…geoengineering is likely to be technically feasible, and could substantially reduce the costs and risks of climate change" (p. 47).

A study by social scientists and philosophers, which was commissioned by the British Parliament, formulated a set of principles as part of a framework for the governance of geoengineering. One of these principles stated that geoengineering should be regulated as a public good and that there should be public participation in decision making (Rayner et al., 2010; Rayner, 2011). This has not prevented strong critiques of the high risks involved in geoengineering (Fleming, 2010; Kwa and van Hemert, 2011). At present, research on geoengineering techniques, such as computer simulations of their projected outcomes, is becoming part of the scientific planning process of the WCRP and the IGBP, along with research on the unintended consequences of geoengineering.

Conclusion

The examples of global warming research and geoengineering show the remarkable extent to which current environmental science has become politicized. It would be unreasonable to expect otherwise: the burden placed on societies, to design and implement mitigation and adaptation strategies for climate change, is not a light one. Since scientific evidence obtained in the laboratory and with the help of mathematical models cannot be simply translated into scientific evidence for public decision making, it is likely that there will be widely divergent societal assessments of risks and uncertainties (Jasanoff and Wynne, 1998; Hulme, 2009). Translation requires the involvement of scientists and politicians, and experts and lay citizens. Political scientist Mark B. Brown has argued that the assumption prevalent in policy advisory processes, that experts do not have interests and politicians and laypeople lack expertise, is wrong (Brown, 2009). Likewise, philosopher and anthropologist Bruno Latour wrote that societies lack the institutions that can 'take into account' the inclusion of new items and concerns into the political process regarding issues that involve the sciences (Latour, 2004). An exception mentioned by Latour is the IPCC, which is unique in that it is at the same time an intergovernmental and a scientific organization. This sympathetic assessment of the IPCC also implies that one IPCC is not enough to guide the development of the environmental sciences and their societal embedding.

Abstract

Environmental sociology, the study of societal-environmental interactions, developed four decades ago in the USA and has spread internationally and become institutionalized around the world. Key foci of the field include examining the social construction of environmental problems as well as analyzing the causes and impacts of, and solutions to, such problems. Major advances in methods and data availability are yielding a rapid increase in our understanding of driving forces and impacts, but there is great debate over potential solutions. The result is an intellectually vibrant field of study.

Environmental sociology emerged in the USA in the 1970s, sparked first by sociological interest in the growth of environmental awareness and activism and then by recognition of the societal relevance of the energy crisis and a growing number of ecological problems (Dunlap and Catton, 1979). It then spread to Europe, where citizen antinuclear protests and Green politics were major foci, and gradually throughout much of the rest of the world. In four decades, it has evolved from a small, marginal field to an increasingly mainstream area. For example, in the USA, many and perhaps a majority of sociology departments in colleges and universities now offer a course in the area, several graduate programs offer concentrations in it, and a growing number of departments are hiring specialists in environmental sociology. Concomitantly, various environmental sociology handbooks (e.g., Redclift and Woodgate, 2010; Gross and Heinrichs, 2010) and numerous textbooks, often in multiple editions (e.g., Bell, 2012; Gould and Lewis, 2014; Harper, 2012), are in print. Most importantly, environmental sociologists are producing a flood of journal articles, increasingly published in elite sociology journals (e.g., Jorgenson and Clark, 2012; Pais et al., 2014; Pellow and Brehm, 2013; York et al., 2003) and research monographs. Parallel trends are occurring in Europe, Asia, and to some degree in Latin America.

The growth and institutionalization of environmental sociology is also evident in terms of organizational developments. The American Sociological Association's Section on Environmental Sociology, founded in 1976 (and now labeled the Section on Environment and Technology), is thriving after modest growth in its first two decades (Dunlap and Catton, 1994), and similar research groups exist within the national sociological associations of several other nations (e.g., Canada and the UK). There is also an environmental sociology research network within the European Sociological Association, while an autonomous Japanese Association for Environmental Sociology has grown into the world's largest organizational body for the field. Most significantly, the International Sociological Association's Research Committee on Environment and Society (RC 24) has quickly grown into one of the largest and most active research committees in the ISA, and provides an excellent forum for the international exchange of ideas and perspectives among practitioners. In short, environmental sociology has become a widely recognized and institutionalized area within the discipline of sociology, and is flourishing not only within several nations but internationally as well.

The institutional and organizational growth of environmental sociology has been accompanied by its intellectual growth and vitality. As the rest of this article will show, the increasing availability of data on environmental problems and ecological conditions has spurred rapid progress in the methodological tools employed by environmental sociologists, while theoretical debates have become more prominent as well. Some of these developments reflect regional differences in methodological and theoretical approaches to environmental sociology across the world, with American and European perspectives being especially notable. I turn to these issues while also conveying the broad contours of the evolution of environmental sociology.

Early Emphases and Disciplinary Context

Modern sociological interest in the physical environment was largely a response to widespread societal awareness of environmental problems, and mobilization of support for environmental protection symbolized by celebration of the 1970 'Earth Day' in the USA and then the 1972 UN Conference on the Human Environment in Stockholm. Early sociological research on environmental topics involved analyses of public opinion toward environmental issues; environmental activism at both the individual and organizational levels; governmental agencies responsible for natural resource management and environmental protection; the roles of activists, media, scientists, and public officials in generating attention to environmental problems; and Green parties and politics (Yearley, 1991). This research applied perspectives from established sociological fields such as social psychology, social movements, political sociology, and organizational sociology to environmental topics, constituting a "sociology of environmental issues" (Dunlap and Catton, 1979).

The 1973–74 energy crisis highlighting the dependence of industrialized societies on fossil fuels, and increasing awareness of the seriousness of air and water pollution throughout the 1970s, ushered in a new strand of sociological research – examining how societies affect their environments and, in turn, are affected by changing environmental conditions such as pollution and resource scarcity. This concern with

 http://dx.doi.org/10.1016/B978-0-08-097086-8.91030-4

societal-environmental relationships reflected the emergence of a true 'environmental sociology,' and by the late 1970s, it was a small but vigorous field (Dunlap and Catton, 1979). Its focus on the relationships between modern societies and their environments represented a major departure from disciplinary norms, however, giving environmental sociology a critical stance relative to the larger discipline.

Sociology became a distinct discipline by emphasizing the social – as opposed to biological, geographical, and psychological – influences on social behavior. It developed during an era of general resource abundance, technological progress, and economic growth. As a result, sociology took root in a cultural worldview which assumed that sophisticated social organization (e.g., complex division of labor) and scientific and technological advances (e.g., nuclear energy) had freed industrial societies from resource and other environmental constraints. This assumption reinforced negative reactions to earlier excesses of 'environmental determinism' such as geographers' efforts to explain cultural differences via climatic variation. The result was that mid-twentieth-century sociology largely ignored the physical environment, and sociological references to 'the environment' typically meant the social context of the phenomena being investigated. More fundamentally, mainstream sociology was premised on a taken-for-granted 'human exemptionalism paradigm' that assumed modern, industrial societies had become exempt from ecological constraints (Catton and Dunlap, 1980).

Sociological analyses of the societal impacts of energy shortages and possibility of ecological 'limits to growth' constituted a significant disciplinary development in the 1970s, and clearly challenged the notion of human exemptionalism. This work was quickly supplemented by research on the social impacts of toxic contamination and other forms of pollution, as well as preliminary examinations of the societal factors generating environmental degradation. A particularly important topic in the USA was environmental justice, with a growing number of studies examining the inequitable distribution of environmental hazards across racial and socioeconomic strata as well as the growth of movements to combat the obvious injustices documented (Mohai et al., 2009). By the early 1990s, many environmental sociologists were ignoring disciplinary norms by analyzing the societal causes and impacts of environmental problems, albeit typically at a local or regional level, representing serious inquiry into societal-environmental interactions (Fischer-Kowalski and Haberl, 1993).

Major Trends and Emphases in the Field

As environmental sociology has evolved, its research emphases have formed around central aspects of environmental (now more typically termed 'ecological') problems: they are caused by human actions, they are treated as problems because of their negative impacts on humans and things that humans value (e.g., other species), solving them requires collective action, and all of the foregoing necessitate societal recognition that various conditions do in fact represent 'ecological problems.' The result is that the bulk of environmental sociology can be seen as focusing on the social construction of environmental problems or analyses of their causes, impacts, and potential solutions.

The Social Construction of Environmental Problems

As noted earlier, sociological interest in the environment was stimulated by societal attention to environmental problems, and much of early sociological work focused on analyzing the manner in which societal recognition developed and evolved. Such work involved studies of environmentalism (both of individual activists as well as environmental organizations), public opinion, and governmental responses (Dunlap and Catton, 1979). Eventually, attention was focused explicitly on the 'social construction' of environmental problems. Building upon such basic observations as levels of airborne particulates being ignored in one era and/or locale but seen as 'pollution' later on or in other places, a rich body of sociological literature has clarified how various environmental conditions become defined as 'problems'; the frequently contested nature of such problems; and the implications of competing interpretations of the sources, impacts, and solutions of the problems. Originally relying heavily on perspectives from social problems and the sociology of science (Yearley, 1991), over time such analyses have drawn on social movement theory, discourse analysis, and cultural sociology.

Numerous studies of claims, claims-makers and claims-making activities have yielded crucial insights into the social processes necessary to generate widespread acceptance of conditions – ranging from local toxic wastes to global climate change – as 'problematic.' Originally, the emphasis was on environmental activists as key claims-makers, but the importance of scientists has drawn increasing attention (Yearley, 2005). The vital role of the media both in publicizing and interpreting claims has also received attention. Such analyses have demonstrated that environmental problems do not simply emerge from objective conditions, but that their recognition is contingent upon issue entrepreneurs and advocacy coalitions (activists, scientists, and policy-makers) being successful in overcoming barriers to getting issues onto the public agenda, and then gaining widespread societal acceptance of their definition of the situation and calls for ameliorative action (Hannigan, 2006).

Early environmental problems like air and water pollution were readily perceptible, but newer problems such as toxic wastes, ozone depletion, and climate change depend on scientific measurements and interpretation for their discovery, analysis, and possible amelioration. The resulting heavy dependence of environmental advocates on scientific evidence has received scrutiny from sociologists. Analysts such as Yearley (2005) have emphasized that the environmental movement's reliance on science is a mixed blessing for several reasons: (1) demands for scientific proof can be used to stall action, particularly by unsympathetic politicians; (2) the probabilistic and tentative nature of scientific evidence falls short of the definitive answers laypeople and policy-makers seek; and (3) reliance on scientific claims makes environmental advocates vulnerable to counterclaims issued by 'skeptic scientists' supported by industry. This has been particularly true of anthropogenic climate change, where contrarian scientists – often backed by fossil fuels corporations and conservative think

tanks – have had considerable success in 'deproblematizing' global warming (McCright and Dunlap, 2010).

Constructivist approaches demonstrate that environmental problems do not simply emerge from changes in objective conditions, that scientific evidence is seldom sufficient for establishing conditions as problematic, and that the manner in which conditions are framed as problems requiring action is crucial. These are major insights, and represent essential sociological contributions. However, in the 1990s, some constructivists followed postmodern fads and 'deconstructed' not only environmental problems and controversies, but 'the environment' (or, more typically, 'nature') itself. Proclamations that "… there is no singular 'nature' as such, only a diversity of contested natures …." (Macnaghten and Urry, 1998: 1) were not uncommon, and posed a challenge to the predominant realist orientation of most environmental sociologists who took the 'reality' of problematic environmental conditions as given even while sensitive to the necessity of such conditions being defined and recognized as problems.

Constructivist excesses provoked a reaction from environmental sociologists of a realist bent, who argued that while one can deconstruct the concept of nature, an obvious human (and culturally bound) construction, this hardly challenges the existence of the global ecosystem and by implication various manifestations of ecosystem change (e.g., ozone depletion) construed as 'problems.' More specifically, a growing chorus of representatives of the realist camp argued that a strong constructivist approach, which ignores the validity of competing environmental claims, slips into relativism, has the potential of undermining environmental scientists and playing into the hands of their opponents, and precludes meaningful examination of societal-environmental relations seen as fundamental to environmental sociology and providing its distinctive focus on the material world (Dunlap and Catton, 1994; Murphy, 2002).

In response to such criticism, many constructivists emphasized that they were not denying the material 'reality' of environmental problems, as their postmodern rhetoric sometimes suggested, but were simply problematizing environmental claims and knowledge. In eschewing relativism in favor of 'mild' or 'contextual' constructivism, most constructivists have moved toward more common ground with their realist colleagues. The latter, in turn, have moved toward a 'critical realist' perspective that, although firmly grounded on acceptance of a reality independent of human understanding, recognizes that scientific (and other) knowledge is imperfect and evolving (Carolan, 2005). The result is that the 'realist–constructivist wars' of the 1990s have subsided; however, a remaining residue is visible in the stances adopted toward utilizing scientific evidence on environmental problems.

From Constructivism versus Realism to Agnosticism versus Pragmatism

The constructivist/realist divide in environmental sociology has evolved into a related but broader pair of stances termed 'agnosticism' and 'pragmatism' based on analysts' treatment of environmental phenomena in their research (Dunlap, 2010). Specifically, those adopting an agnostic stance (especially prevalent among but not confined to European scholars) toward environmental problems are reluctant to employ scientific indicators of these phenomena, preferring instead to problematize, contextualize, and sometimes deconstruct scientific evidence regarding issues such as anthropogenic climate change. For example, their analyses offer valuable insights into the complexities and contingencies of climate science, but because they are hesitant about granting ontological standing to the claims of climate scientists they avoid examining the causes and likely impacts of rising greenhouse gas (GHG) emissions (Yearley, 2009).

In contrast, the pragmatic approach, which is popular with (but not limited to) American scholars, employs the best available scientific data on a wide range of environmental conditions – carbon dioxide and other GHG emissions, deforestation, toxic wastes, and so on – in empirical analyses to investigate their relationships with an array of social phenomena. While many of these analyses of societal-environmental interactions involve rigorous statistical analyses of large, quantitative data sets, pragmatists also perform more qualitative, in-depth case studies that provide rich insights into the evolution of such interactions over long periods of time (Freudenburg et al., 2009).

The agnosticism about the state of environmental conditions that has roots in the postmodernist turn of the larger discipline, and the popularity of constructivist analyses within environmental sociology so prevalent in the 1990s, continues to have pervasive effects on sociological research and theorizing about societal-environmental relations. This is particularly true among European scholars, where there is far less work on the material dimensions of environmental problems (see Fischer-Kowalski and Haberl, 2007 for a notable exception). Instead, the agnostic camp tends to treat environmental matters as symbolic/ideational/cultural phenomena, to be analyzed via hermeneutic/interpretative approaches. Its efforts to incorporate the material world into sociological analyses are often limited to the discursive realm via talk about 'hybrids,' 'cyborgs,' and such (Dunlap, 2010).

So strong is this agnostic stance in Europe that even theorists holding a presumably more realist bent adopt agnostic positions toward the utility of scientific data for the study of environmental phenomena. For example, proponents of ecological modernization theory (EMT) (discussed below) tend to advocate skepticism toward rigorous empirical analyses of environmental conditions in favor of methods that are more qualitative and subjective. Leading ecological modernization theorists Mol and Spaargaren (see Mol et al., 2009), for example, express skepticism about the ability of empirical research to settle theoretical debates and largely reject the use of empirical methods and hypothesis testing in analyses of the environmental consequences of modernization. They further question the validity of using "natural science 'empirical facts'" and quantitative analyses to assess socially generated environmental problems (see quotes in York et al., 2010: 80).

Such a stance (not unique to Mol and Spaargaren) is at odds with the large and growing body of sociological research that relies heavily on measures of environmental conditions produced by natural scientists, government agencies, and sometimes environmental activists to analyze empirically diverse and often competing perspectives on the causes or driving forces of environmental degradation (e.g., York et al.,

2003), the impacts of degradation (Pais et al., 2014), and mechanisms of environmental reform (e.g., Roberts et al., 2004). While empirically oriented pragmatists within environmental sociology can benefit from the cautions raised by agnostics concerning the pitfalls of employing imperfect data on environmental conditions, the gulf between the two 'camps' concerning the utility of empirical evidence for testing theoretical perspectives and adjudicating debates between competing perspectives clearly poses a challenge for the field.

Causes or Driving Forces of Environmental Problems

From the outset, environmental sociologists have focused attention on the societal factors that produce environmental degradation (Dunlap and Catton, 1979: 252), although early work was hampered by a paucity of data on environmental conditions. Consequently, early work tended to examine arguments being put forth by natural scientists, particularly biological ecologists like Paul Ehrlich and Barry Commoner. Most influential in this regard was Schnaiberg's (1980) analysis of the weaknesses of emphasizing population growth, technological development, and materialistic consumption patterns as the key drivers of degradation. In contrast, Schnaiberg drew on political economy perspectives to develop a sophisticated alternative that stresses the inherent need for market-based firms to grow, to replace costly labor with advanced technologies, and to increase their use of resources and production of pollution in an ever-expanding production process. He argued that a powerful coalition of capital, state, and labor forms a 'growth coalition' that promotes and defends the resulting 'treadmill of production,' which yields endless growth (and escalating environmental degradation).

The treadmill model has been supplemented by a range of more explicitly Marxist analyses, including O'Connor's (1991) 'second contradiction of capitalism' notion, which argues that increasing the scale of production raises production costs and levels of pollution, as more expensive and difficult-to-obtain resources are continually substituted as those most accessible are depleted (1997). Like the treadmill, the second contradiction points to the unsustainability of endless economic growth. In a complementary fashion, Foster's use of Marx's concept of 'metabolic rift' clarifies the manner in which production and consumption in capitalist systems are inherently unecological (Foster et al., 2011). All three perspectives converge to provide a 'political economy' model that suggests that Capitalist-driven economic growth is the key factor producing environmental degradation worldwide, and the global free-market economy is the primary barrier to slowing such degradation and achieving ecological sustainability.

The resulting model, focused originally on the USA, has been extended to the international level with a marriage with World Systems Theory and its derivatives such as ecologically unequal exchange to create a global political economy model now widely used within environmental sociology (Jorgenson et al., 2014). With the growing availability of a wide range of data on resource use, pollution production and overall ecological impact at the level of nation-states, quantitatively sophisticated cross-national research has provided considerable insight into the driving forces of deforestation, GHG emissions, and ecological footprints (Jorgenson and Clark, 2012). A critical insight has been the degree to which the wealthy 'core' nations are able to protect their own environmental quality by using poorer, peripheral nations as both sources of natural resources and as sinks for pollution (Jorgenson and Clark, 2011). Such studies reinforce the pessimistic implications of the political economy model at the international level, suggesting that the global growth of a Capitalist-driven free-market economy is ecologically unsustainable as well as highly inequitable.

An alternative model of the driving forces of environmental degradation has evolved directly from the work of biologists such as Commoner and Ehrlich, particularly their famous 'IPAT' equation, which viewed (negative) environmental impacts as a function of population, affluence, and technology. Environmental sociologists have drawn on human ecology to develop a stochastic 'STIRPAT' model (technically, the STochastic Impacts by Regression on Population, Affluence and Technology model) allowing for predictions of a variety of environmental impacts, ranging from ecological footprints to GHG emissions to fertilizer and pesticide use (York et al., 2003). Such analyses reveal that population and affluence both have strong, positive effects on the ecological impacts of nations, and thus supplement rather than contradict findings from the political economy perspective by suggesting that growth of all types (whether in population, affluence, consumption) is incompatible with ecological sustainability.

As will be discussed below, both of the dominant strands of research on the driving forces of environmental degradation yield results that contrast with the more sanguine views offered by proponents of EMT. EMT not only fails to view Capitalism as inherently ecologically destructive, but suggests that a market economy coupled with technological innovation offers the best hope of solving environmental problems and moving toward a more sustainable future (Mol et al., 2009). EMT is examined in the section on 'solving environmental problems.'

Impacts of Environmental Problems: Inequitable Distribution and Environmental Justice

A key dimension of early work by environmental sociologists was a concern with the social impacts of environmental and resource problems, particularly the distributional aspects of negative impacts. Inequality has long been a central focus of the larger discipline, and it is thus no surprise that the inequitable impacts of energy shortages and the regressive impacts of policies to deal with them were major concerns in the 1970s (Dunlap and Catton, 1979: 263). With the discovery of toxic contamination in Love Canal and other communities, the distribution of exposure to environmental hazards became a central focus of environmental sociology. Numerous studies have documented the inequitable manner in which toxic wastes and other environmental hazards are distributed across racial and socioeconomic strata, with minorities and lower socioeconomic levels being disproportionately exposed to them (Mohai et al., 2009). Debates remain over whether race or class is the crucial factor, and increasingly sophisticated studies have helped clarify the complex interplay between these factors as well as the role of historical trajectories in influencing contemporary patterns of inequitable exposure (Pais et al., 2014).

Work in the realm of what is now termed environmental justice research has become methodologically rigorous, due to sophisticated analytical techniques and improved data availability, especially the use of geographic information systems (GIS) to overlay biophysical data with socioeconomic data across geographical units ranging from neighborhoods to census tracts. Such advances allow, for example, researchers to clearly identify urban 'heat islands' in which residents are exposed to dangerously high temperatures during heat waves and the socioeconomic characteristics of these neighborhoods – typically disproportionately populated with poor, racial minorities, elderly and isolated individuals (Harlan et al., 2013). Such technically strong work has advanced our knowledge of environmental 'injustices' immensely, and has been complemented by advances in theorizing the origins of environmental injustice and examinations of the emergence and international diffusion of social movements pursuing the goal environmental justice (Mohai et al., 2009).

At the other end of the geographical spectrum, a large and growing body of research and theorizing focuses on inequities in generating environmental degradation and experiencing the effects of such degradation throughout the global system. Intimately related to the previously noted work on driving forces, this scholarship has consistently documented inequities in the global economic system that benefit wealthy nations at the expense of poorer nations. Poor nations are pressured to engage in ecologically unequal exchanges with wealthy nations, providing their natural resources as inputs for use by multinational corporations (sometimes for materials produced in factories in their own nations, other times shipped abroad) in efforts to improve their own economies – but often with little success. At the same time, resource extraction generates environmental degradation as does the use of their territory as 'sinks' for international pollution, whether in the form of housing polluting factories that ship goods abroad or as actual dumping grounds for hazardous materials from wealthy nations (Jorgenson et al., 2014). Rising awareness of such processes is stimulating environmental justice campaigns around the world.

Beyond an explicit focus on equity, sociological work has documented the deleterious impacts of environmental problems created by human-created technological accidents and hazards. Unlike natural disasters such as floods, earthquakes, tornadoes, and hurricanes – which have been found to produce a therapeutic response in the affected communities, uniting the populace in helping victims and repairing damage – technologically induced disasters like release of toxic wastes tend to have a corrosive effect on community life. The frequent ambiguities inherent in documenting the sources and seriousness of the contamination often generate conflict among different sectors, especially those economically dependent on the perceived source and those most affected by the contamination. In-depth qualitative studies have documented the long-term erosion of community life and personal tolls on residents (Freudenburg, 1997).

Solving Environmental Problems

In the USA, environmental sociologists have paid less attention to possible solutions to environmental problems than to their causes and impacts, and early work on energy policies emphasized their regressive impacts rather than efficacy (Dunlap and Catton, 1979). Currently, various strands of relevant research, from a microlevel focus on developing 'behavioral wedges' to stimulate residential energy conservation (Dietz et al., 2009) to macrolevel analyses of the forces promoting and hampering the adoption of international environmental treaties (Roberts et al., 2004), are in progress. However, attention to solutions took a quantum leap forward when European environmental sociologists began analyzing and generalizing from instances of significant environmental reforms in some Northern European nations. The result was the emergence of EMT, a perspective that has enjoyed widespread visibility in Europe and, increasingly, in the rest of the world (Mol et al., 2009).

EMT called for a refocusing of the field, from analyzing the sources of environmental degradation to examining the sources and mechanisms of environmental reform. Building on industrial ecology models suggesting that production can grow with declining input of materials and resulting pollution, EMT quickly supplemented such claims of 'dematerializing' the economy via technological innovation with analyses of complementary societal developments. New forms of collaboration between industry, government, and civil society were seen as institutionalizing an 'ecological rationality' driven by science and technology that not only tempers environmentally harmful decision making, but stimulates a 'green capitalism' that marries the power of the market with the pursuit of environmental quality (Mol et al., 2009). EMT became popular in both academic and policy circles, in part because it not only sees Capitalism as friend rather than foe of environmental progress – a message that resonates well with powerful interests in an era of hegemonic free-market ideology – but embodies optimistic projections directly counter to the pessimistic views of both the political economy and human ecology perspectives. Such tendencies have led to it being portrayed as a very conservative approach to the possibility of achieving significant change in the current economic system (Foster, 2012).

Based on evidence from Northern European nations, EMT appeared to offer a welcome alternative to dominant perspectives in the field. Not surprisingly, however, its optimistic claims met with skepticism among American scholars, and critics soon pointed to the limitations of case studies of 'success stories' (whether individual factories or nations) and the focus on institutional outcomes (e.g., new laws and agencies) and behaviors (from establishment of corporate environmental officers to green consumerism). In contrast, a growing number of empirical studies examining actual environmental conditions such as GHG emissions and ecological footprints consistently find that economic growth produces higher levels of environmental degradation, especially at the global level (Jorgenson and Clark, 2011, 2012; York et al., 2003), and that improvements in environmental quality within some wealthy nations have come at the expense of their ecological loads being shifted to poor nations and the global commons (Jorgenson and Clark, 2011; York et al., 2010). Critics have further argued that in nations such as the USA, where free-market forces reign supreme, the sources of ecological rationality – environmental science, environmental pressure groups, and environmental agencies – are under constant

assault, threatening to create a process of ecological *demodernization*. The result is that not only does *unecological* modernization (i.e., growth as usual) continue, but ecological irrationality (like denial of anthropogenic climate change) is increasingly institutionalized (McCright and Dunlap, 2010).

These empirical tests and empirically based criticisms have produced something of an impasse, as leading proponents of EMT tend to dismiss the mounting number of studies disconfirming their optimistic projections. While not postmodern relativists, they have nonetheless adopted a very agnostic stance toward the use of scientific measures of environmental indicators and questioned the utility of empirical testing of theories as noted earlier (and documented in York et al., 2010). Unlike strong constructivists, who limit their analyses to the discursive realm, EMT proponents tend to limit theirs to the institutional and cultural realms and proclaim progress when regulations are adopted or green consumerism becomes more popular – without carefully assessing whether these developments produce discernible reductions in ecological impacts, especially at the global level (which is the bottom line when assessing the impacts of continued economic growth). Thus, to American 'realists,' EMT seems naively optimistic and lacking in empirical support, with its refusal to acknowledge troubling evidence of continuing ecological degradation representing a new version of human exemptionalism (Foster, 2012). Nonetheless, EMT may offer useful suggestions for developing nations that seek to lower their environmental impacts, such as China where it seems to be making inroads (Hong et al., 2014).

Complementing EMT is world polity theory (WPT), which posits the emergence of an evolving world culture that diffuses international norms concerning the duties of nation-states, including environmental protection. Emphasizing the role of both governmental and nongovernmental agents (international treaties, intergovernmental organizations, transnational environmental organizations, etc.), proponents of WPT argue that an international 'environmental regime' has been established that fosters environmental protection worldwide. Several empirical studies have documented the global diffusion of environmental protection mechanisms, including increased levels of activism from civil society sectors (especially environmental nongovernmental organizations) that put pressure on governments in less-developed nations to strengthen environmental protection efforts. The degree to which such activities can counteract the ecologically harmful unequal exchange relationships imposed on these nations by the global economic system and yield actual improvements in environmental quality still remains unclear (Jorgenson et al., 2014; Knight and Messer, 2012).

In addition, nations that were once innovators in environmental protection (especially the USA in the early 1970s), and thus major sources of stimulation for the establishment of an international environmental regime, are now reversing course as their governments are taken over by antiregulatory, free-market advocates. Watching the increasingly successful efforts of the American Right to dismantle environmental protection regulations and agencies in the USA (McCright and Dunlap, 2010), and the spread of similar efforts to other nations with neoliberal regimes such as Canada and Australia, makes this reversal a significant possibility – as witness the obstructive roles currently being played by these three nations in international negotiations on climate change policy.

Clearly there is need for additional sociological work on efforts to solve environmental degradation, especially to assess the likelihood that increasing ecological deterioration at the global level (e.g., rising GHG concentrations) can not only be slowed but eventually halted, particularly with a global economic system premised on endless growth. Thus far the empirical evidence on global trends does not match the optimistic projections of EMT and WPT (Jorgenson and Clark, 2011, 2012; Jorgenson et al., 2014; York et al., 2003, 2010).

Improved Data and Increasing Methodological Sophistication: An Illustration

At the beginning and throughout this article, reference has been made to the impact of the availability of improved data sets, especially on environmental conditions, and increasingly sophisticated methodological tools on the field of environmental sociology. For empirically inclined scholars, these trends are revolutionizing the field of environmental sociology and promise to continue to do so. Their impact is especially apparent in work on one of the oldest topics in the field, environmental attitudes and behaviors. Early work on public opinion evolved into efforts to carefully conceptualize "environmental concern" (Dunlap and Jones, 2000) and to develop theoretical models to predict and explain both the attitudinal and behavioral components of such concern. While European scholars often employed rational choice theory in both surveys and experimental studies of behaviors (Diekmann and Schmidt, 1998), Americans developed models of pro-environmental behavior building on theories of values and norm activation (Stern et al., 1999), while both contributed to clarifying key demographic predictors of environmental concern such as age, education, and political orientation.

The emergence in the 1990s of multinational data sets on citizens' views of environmental issues led to cross-national studies becoming popular. A debate evolved between Europeans working from a rational choice perspective viewing citizen concern as a result of affluence, and thus more prevalent in wealthy nations (Franzen and Meyer, 2012), and Americans viewing such concern as stimulated by awareness of environmental degradation, and thus widely distributed across nations and often higher in poor nations (Dunlap and York, 2008). The contrasting results are partially attributable to differences in the measures employed, with indicators of willingness to pay favored by proponents of the affluence perspective and a wider range of indicators used by proponents of the globalization perspective (Knight and Messer, 2012).

Increasingly, multilevel models examining the relative impact of national characteristics such as economic affluence and environmental degradation and individual characteristics such as values and income are being conducted. These studies provide rich insights into the interplay of personal characteristics and national contexts, showing, for example, that while *national* affluence does *not* lead to higher levels of citizen concern for the environment, within nations there may be (depending on the measure used) positive relationships

between postmaterial values and *individual* income and environmental concern (Fairbrother, 2013). More work along these lines, especially with improved data on environmental degradation within nations, should clarify the factors that enhance citizen support for environmental protection and how these vary with national and regional contexts.

Concluding Observations and Future Projections

The foregoing review has been limited to major emphases and controversies within the field of environmental sociology, particularly trends in research on the causes and impacts of environmental degradation and controversies regarding sociological work on potential solutions. It is worth highlighting three important issues: First, the increasing methodological sophistication of many practitioners and the ever-growing bodies of data on ecological conditions is yielding unprecedented advances in our understanding of the driving forces and impacts of ecological problems. Second, while the constructivist–realist divide has subsided, differing stances toward the utility of employing indicators of ecological conditions in empirical testing of theoretical perspectives are readily apparent, and hamper productive debate between agnostics and pragmatists. Third, and related to the second, the current major theoretical cleavage within the field is over the ability or inability of ecological modernization processes to halt environmental degradation, especially at the global level.

There are other aspects of environmental sociology worth noting, including the fact that over and above the just-noted differences, there is great diversity in methodological and theoretical approaches with strong bodies of work being produced by both qualitative and quantitative researchers, at the mirco- and macrolevel, and employing both constructivist and realist approaches. This diversity is enhanced by the geographical diffusion of the field, especially beyond North America and Europe (Dunlap, 2010). In Japan, for example, one can find scholars making heavy use of Western perspectives (Hasegawa, 2004) as well as developing indigenous ones (Torigoe, 2014). As environmental sociology becomes an ever more international field, one can expect this intellectual diversity to grow and produce beneficial effects.

There is also great variation in the degree to which environmental sociologists adopt multidisciplinary perspectives and engage in interdisciplinary projects. While some scholars focus on testing sociological theories such as WPT and do not venture outside of the discipline, others adopt research programs that inherently cross disciplinary boundaries (Fischer-Kowalski and Haberl, 2007). Given that the core focus of environmental sociology on societal-environmental interactions is now shared by a range of disciplines involved in 'coupled human and natural systems' research, and that many concerns of our field overlap with the growing area of 'sustainability science,' it is not surprising that environmental sociologists are actively engaged in these broader efforts (Liu et al., 2007).

In short, it seems appropriate to conclude that the field of environmental sociology, now in its fourth decade, has established itself as a respectable and intellectually vibrant field of study. The discovery of new ecological problems, and the recalcitrant nature of current ones, ensures that the field's subject matter will only grow in societal importance. One can only hope that as the field moves forward, it will be able to make more significant contributions to dealing with these problems, raising its profile beyond academia.

Abstract

This article examines the relationship of environmental stress to disturbances in behavior, mental health functioning, and public health for people impacted by a variety of ecosystem disruptions. The biophysical environment has enduring characteristics that are intimately linked to human social systems. Economic, social, cultural, and spiritual connections between the 'social' and 'biophysical' environments have been compellingly identified in the literature. Such exchange relationships between natural and human systems establish continuous dialectical interactions, which often results in changes to both. Extreme environmental stress in the form of catastrophic natural and technological disasters seriously undermines the human condition and quality of life in the modern world. We will briefly identify the context of contemporary risk and review the health consequences of extreme environmental stress.

Risk and Environmental Stress

The changing nature of risk in late modernity has been chronicled in the writings of Ulrich Beck (1992) and Kai Erikson (1994). Beck notes that 'manufactured' (human-generated) risks threaten the safety of the biophysical environment, while Erikson identifies the consequences of such risks for humans as a 'new species of trouble.' The relatively recent emergence of human-generated environmental risks and the extensive depletion of natural resources have produced stress and disruption to ecosystem services, social organizations, and the dynamic relationships between these entities (Kroll-Smith and Couch, 1993).

As defined by Beck (1992), modern environmental risks are characterized by new issues and concerns for human communities. First, these new environmental stressors are global, invisible, and often undetectable by human sensory perception. Second, they transcend generations; for example, massive amounts of radiation can impact future generations through an increased likelihood of birth defects. Third, such risks preclude causal attribution so that survivors can never be adequately compensated for damages (Beck, 1992). Downstream toxic contamination involves myriad sources of air, water, and soil pollution, while death, declines in public health, psychological pathology, and the loss of community are not compensable damages. This insidious 'collective trauma' invades the human condition on a permanent basis, separating the self from others, eroding trust and social relationships through the establishment of uncertainty and dread as social norms (Erikson, 1994).

Such anthropogenic environmental stress can alter traditional patterns of social organization by draining social capital and producing systemic corrosive communities (Freudenburg, 1997). This recognition of the potential untoward consequences of manufactured risks for both the natural and social environments has resulted in a reconsideration of the types of disasters that will characterize the twenty-first century. Traditionally viewed as 'natural' (meteorological and seismological events) or 'technological' (human-caused contamination), modern disasters now include a variety of hybrid 'natech' disasters, as well as acts of terrorism. Although terrorism is not a 'new' political event, the post-9/11 disaster landscape must include these purposeful, violent acts as human-caused destruction that involves the release of toxic chemicals and massive devastation of the built environment (Marshall et al., 2003). Furthermore, hurricanes, floods, and tsunamis will potentially impact chemical production and energy facilities, which, in turn, release toxins and radiation into the environment. Hurricane Katrina and the Fukushima tsunami are two obvious examples of these modern natech disasters (Picou, 2009a).

When we relate these catastrophic types of disasters to environmental stress, it becomes apparent that such events have enduring characteristics, which are beyond the control of residents of impacted communities. Although people may consider the toxic contamination produced by technological, terrorist, and natech disasters as harmful to their health and well-being, they can actually do very little to cleanup or reduce continuing radioactive and toxic emissions. The reaction by government and corporate authorities is often framed within a narrative that exposure poses little or no threat to ecosystem vitality or public health, and that the cleanup and containment of toxins, radiation, etc. has been successful. Such admonitions only exacerbate the fears and uncertainties of a distrusting public, resulting in long-term corrosion of the social fabric. Such secondary disasters stall timely ecological and community recovery from these extreme forms of environmental stress. In short, the consequences of modern technological, terrorist, and natech disasters become debated or contested in their aftermath. From official accounts of damages to protracted adversarial litigation, there is no consensus achieved on the final consequences of the event (Picou, 2009b).

A summary of these catastrophic types of disasters is presented in **Table 1**. Developed by Erikson (1994), this 2×2 property space identifies the cause of the disaster (natural or human) and type of destruction (toxic or nontoxic) as the defining characteristics of catastrophic environmental stress. Secondary disasters result from toxic contamination produced by both natural and human causes, and a continuing spiral of social impacts emerge (Gill, 2007). Indeed, human communities lose social capital, while residents experience

Table 1 Erikson's classification of disasters

	Cause	
Toxicity	*Human (technological)*	*Nature*
Nontoxic	Fires, dam collapses, airplane crashes, explosions	Hurricanes, floods, tornados, earthquakes
Toxic	Oil spills, toxic chemical spills, radiation leaks, toxic waste contamination, terrorism	Radon gas, natech scenarios – natural disasters that cause a technological disaster

Erikson, K.T., 1994. A New Species of Trouble: Explorations in Disasters, Trauma, and Community. W.W. Norton, New York.

deleterious medical and mental health consequences (Adeola and Picou, 2012, 2014).

The Context of Psychological Stress

Although there are many interpretations of how environmental risks and disasters impact people in the fields of medicine, sociology, and psychology, the Conservation of Resources (COR) stress model has been successfully used in research over the last 35 years (Hobfoll, 1989). As an explanatory framework, the COR model identifies resource loss, the threat of resource loss, and resource investment failure as primary determinants of psychological stress. This model considers four basic resources: (1) Objects (e.g., physical possessions, natural resources), (2) Conditions (e.g., good marriage; quality relationships), (3) Energies (e.g., money, knowledge), and (4) Personal characteristics (e.g., self-esteem, confidence). This comprehensive model predicts that psychological stress occurs when environmental risks and disasters alter values, produce extreme demands on individual and collective resources, overburden resource use, and produce strong mental damage (Hobfall, 1991). A variety of pathological psychological outcomes are predicted by the COR model, including anxiety, severe depression, posttraumatic stress disorder (PTSD), self-isolation, and anger. With technological, terrorist, and natech catastrophes comes acute uncertainty and dread on the part of survivors regarding the nature and extent of contamination and the future impacts of these forms of extreme environmental stress (Marshall and Picou, 2008).

Definitions of Environmental Stress

Although there are many different concepts of stress in the respective fields of medicine, psychology, and sociology, it is generally understood that stress is aversive for many people. Psychologists often employ the stress concept proposed by Lazarus (1966) and Lazarus and Launier (1978), which defines stress as a transaction between stimulus and response, i.e., the process that reflects the individual appraisal of a stimulus by persons who see an imbalance between environmental demands and their own response capabilities to cope adequately with the demands. A variety of mental health outcomes are associated with the recognition of loss or threat of loss to multiple types of resources conditioned by these stimulus/response transactions. These negative stimuli disrupt routine behavior and range from modest ambient stressors to cataclysmic events such as those noted above.

Characteristics of Environmental Stressors

Ambient stressors reflect continuous and intractable background characteristics of the physical environment (Campbell, 1983). Often unnoticed, the continuous hum of air conditioners, the permanent dust in an industrial area, and the faint hiss of the central heating system are common examples. People often adapt to ambient stressors, and they consider the costs of coping with such stressors to be more problematic than simply enduring them.

In addition, each type of environmental stressor can be categorized along several dimensions.

1. The major dimension is the degree of controllability over the environmental stressor (Campbell, 1983). Control may be either direct (e.g., switching off the neighbor's noisy lawn mover), indirect (e.g., closing the windows in order to reduce the noise penetration), social (e.g., calling authorities to stop the noise), or cognitive (e.g., knowing that the noise will stop in about an hour). Oftentimes, stress effects decrease with increased control, but control may have secondary stress effects (e.g., closing the windows will increase the temperature inside the house).
2. Related to cognitive control is the predictability of the stressor. High predictability of the occurrence and duration of an aversive agent may help people cope. For instance, residents in the vicinity of urban rail systems usually know the schedule of the trains and seldom complain about noise and vibration. Alternatively, knowing beforehand that a new airport will open in the neighborhood may cause greater stress effects than knowing that the old airport will close in the neighborhood (Hatfield et al., 1998).
3. Stressors may be more or less perceptually salient or identifiable. Some environmental agents are of rather low intensity and may either be not detected at all (e.g., low radioactive radiation), while others are only detected when intensity changes (e.g., the faint current of air conditioners). If an environmental agent is not perceptually salient, stress reactions may occur because people get informed about potential hazards. Such is the case for invisible and unknown toxic contamination.

Stressful life events also include incidents in the life cycle that require individual adaptive responses. Such events include changes in work, or residential environment, such as beginning a new job, moving to a new residential area, new construction work in the present residential area, or a perceptible change in the operating conditions of a nearby stressor. The event as such is usually short, but the behavioral consequences may extend through time.

Daily hassles are repeatedly occurring aversive events of ordinary life, such as arguments with colleagues, crowded classrooms, and traffic congestions on the route to work. Although they typically are more or less predictable, the individual has little means to avoid such hassles and their duration is rather short.

Variables Intervening between Stressors and Their Effects

Although varying degrees of environmental stress result in different social responses, it is also documented that the same stress exposure does not cause the same reaction in every person or in every situation. Situational, personal, and social variables determine whether an environmental agent becomes a severe problem for a person or a community.

There are variations in vulnerability to environmental stressors that characterize human populations (Donner and Rodriguez, 2008). The vulnerability model of environmental stress identifies socioeconomic status, gender, race, and age as examples of demographic vulnerability to extreme events (Thomas et al., 2013). On the other hand, the concept of resilience identifies the capacity of individuals, communities, and regions to resist, respond, absorb, and recover from extreme environmental stress. Resilient groups have the capacity to respond to environmental stress and recover from extreme disturbances in a timely fashion.

The Capital-Based Approach to Environmental Stress

Disaster researchers have identified five predominant forms of capital relevant to environmental stress: social, economic, physical, human, and natural (Portes, 1998; Aldrich, 2012). Social capital refers to the resources and abilities available to social groups through networks, trust, reciprocity, common values, and consensual rules (Bourdieu, 1986). Economic capital identifies the capacity to access financial resources, while physical capital refers to the scope and capacity of the built and modified environments. Natural capital refers to the abundance and availability of natural resources, while human capital refers to the coordination of all forms of capital to promote economic production. These forms of capital identify components for understanding vulnerability to extreme environmental stressors and the building of resilient responses to such events (Ritchie and Gill, 2007).

Case Studies of Catastrophic Environmental Stress

The following case studies briefly describe events that produced catastrophic environmental stress over the last 35 years.

Living in Contaminated Areas

Residential areas are sometimes built either on or in the vicinity of former industrial areas, and this can cause severe public health problems. One of the more infamous examples is Love Canal (Levine, 1982), a neighborhood in Niagara Falls, New York. This residential area was used by Hooker Chemical Company to bury 21 000 tons of assorted toxic waste. The emergence of chemicals in the air, water, and soil were detected in 1978, and health authorities warned the residents about the exposure risk. Over 900 families were evacuated. Despite attempts to cleanup this environmental tragedy, current residents have filed lawsuits and the physical and mental health impacts have had serious consequences for many residents (Levine, 1982). These negative outcomes include cancer, heart disease, anxiety, and severe depression.

A more recent example of residential contamination comes from the Wingate community in Fort Lauderdale, Florida. A municipal incinerator operated in this neighborhood for over 24 years and subsequent environmental testing revealed dioxin, mercury, arsenic, furans, and other carcinogenic compounds in the water and soil (Bevc et al., 2005). Research conducted 30 years after the closing of the incinerator found that physical symptoms of medical illness were related to exposure to chemicals, consumption of contaminated food, and mental health problems (Bevc et al., 2005). The human impacts of living in contaminated communities are serious for both the medical and mental well-being of residents and persist for extended periods of time (Edelstein, 2003).

Living with Nuclear Power Plants

Although the nuclear industry spends billions of dollars for public relations in the hope of changing public attitudes regarding the safety of nuclear power plants and nuclear waste, the general attitudes in Western societies remain skeptical. Such public responses are caused by the experience of technological catastrophes like Three Mile Island (TMI) in 1979 and Chernobyl in 1986. Seven years after the catastrophe at TMI, residents living near the damaged reactor reported more chronic stress symptoms and sleep disturbances than did control subjects (Davidson et al., 1987). The final health impacts of Chernobyl will never be known. However, increases in thyroid cancer have been documented in addition to those deaths reported in the first 4 months following the meltdown. Over 350 000 people were eventually evacuated from the highest radiation-contaminated areas. The psychological effects of these technological catastrophes on residents differ from those of natural hazards in many ways, e.g., they are more long lasting, and residents lose faith in public communications of authorities with respect to safety and control of health risks (Erikson, 1994).

The catastrophe at Chernobyl caused severe psychological changes in the European population, especially with respect to the evaluation of nuclear power, the probability of a nuclear accident, and the health risks for children (Drottz-Sjöberg and Sjöberg, 1990; Hüppe and Janke, 1994). Many social scientists believe that the inconsistent risk communication policies of public authorities has contributed to the stress symptoms of residents who were minimally exposed to direct nuclear radiation. At this time, the TMI-2 reactor is permanently out of operation and contains no radioactive materials or waste. The Chernobyl reactor is covered by a concrete sarcophagus, which will be replaced with a new, safer shelter in the future.

When Oil Invades Our Water

On 24 March 1989, the supertanker *Exxon Valdez* slammed into a well-marked reef in Prince William Sound, Alaska. Over 11 million gallons of crude oil were released into one of the most pristine marine ecosystems in North America, causing massive death and destruction of fish, birds, and a wide variety of marine mammal populations. Over 25 years of longitudinal research on ecological and social impacts clearly reveal severe consequences for both the natural and human environments. Four years after the *Exxon Valdez* oil spill, the

herring fishery collapsed, and to date this critical commercial and subsistence fishery has not recovered. Toxic impacts continue to be documented for sea otters, harlequin ducks, and many other species that are still being exposed to lingering oil in the spill area (Rice, 2009).

Research on the social and psychological impacts of the *Exxon Valdez* spill clearly reveal long-term economic, mental health, and community impacts. High levels of PTSD, depression, and community conflict persisted in Cordova, Alaska, for nearly 20 years after the spill (Picou, 2009b). As ecological impacts emerged over time and the protracted civil litigation continued until 2008, commercial fishers, Alaska Natives, and plaintiffs in the litigation were found to be at high risk for psychosocial damages (Picou et al., 2004; Gill et al., 2014).

On 20 April 2010, the Deepwater Horizon drilling platform, located 50 miles off the Louisiana Coast in the Gulf of Mexico, exploded, resulting in the release of approximately 200 million gallons of oil over a 3-month period. The immediate socioeconomic impacts for commercial and recreational fishing, tourism, and other coastal industries were devastating. Indeed, in the months after the explosion severe mental health impacts, similar to those of the *Exxon Valdez*, included uncertainty, PTSD, and suicides (Gill et al., 2011). The ecological consequences of this extreme form of environmental stress for the Gulf of Mexico will be monitored for many decades in the future. Furthermore, like the earlier *Exxon Valdez* spill, litigation will also continue well into the future, creating a context for prolonged disruption and stress for coastal residents.

Hybrid Forms of Environmental Stress

Natural disasters often have destructive consequences for chemical production systems, oil refineries, and local sources of toxic chemicals. This 'natural–technological synergy' results in technological failure, ecological contaminations, and toxic exposure for humans, creating a worst-case context for environmental stress. Air pollution, sediment contamination, and the movement of chemicals through the floodwaters of New Orleans from Hurricane Katrina created a classic natech disaster. In short, Hurricane Katrina was not only a massive meteorological event, but also a massive contamination event. The fact that Hurricane Katrina caused the release of 8 million gallons of oil is often overlooked by disaster researchers. At that time, this was the second largest oil spill in North American history, with only the 1989 *Exxon Valdez* releasing more oil (Picou, 2009a).

Earthquakes are another natural occurrence that can precipitate a natech disaster. Such was the case when a magnitude 9.0 earthquake struck off the coast of Japan on 11 March 2011. The quake generated a 50-foot tsunami which, in turn, damaged the Fukushima Daiichi nuclear power plant, resulting in a massive release of radioactive contamination. In addition to that released, a vast amount of radioactive water is being stored at the site. Cleanup and decontamination are expected to take decades. While there have been no deaths attributed directly to the radioactive release, hundreds died as a result of the ensuing evacuation and relocation of area populations. In addition, those exposed to radiation will experience severe stress and anxiety associated with the increased risk of cancer and birth defect for the rest of their lives and into the next generation.

Conclusions

Environmental stress must be framed in the context of modern risk. The global, uncontrollable, and invisible nature of contemporary risks produces extreme forms of environmental stress that threaten public health. The dual risks of natural and technological disasters will continue to challenge ecological resources and the social well-being of human populations throughout the twenty-first century.
